

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

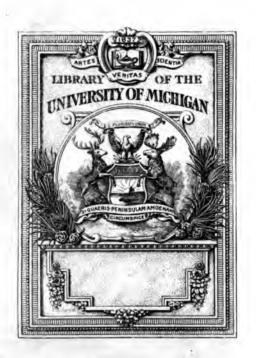

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + Refrain from automated querying Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

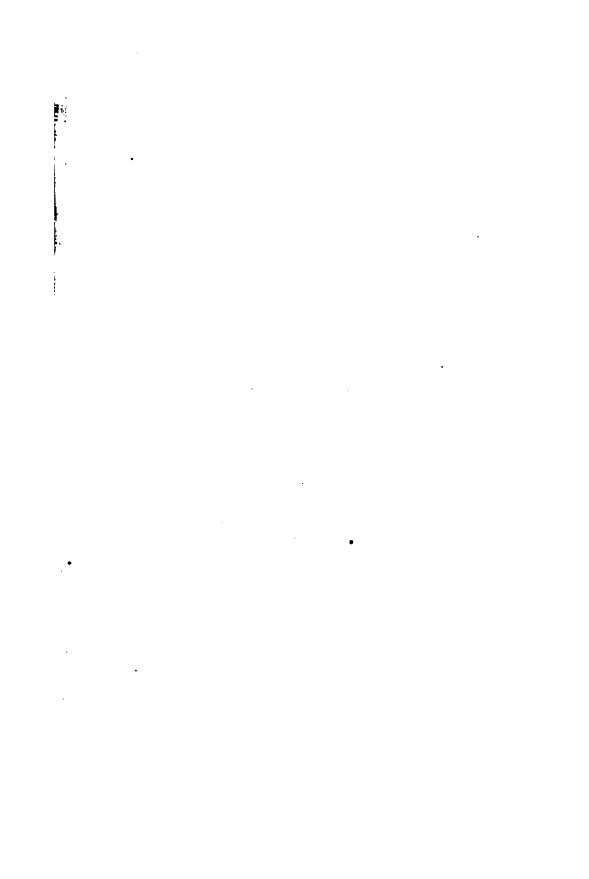

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

ANNUAL REPORT

OF THE

GEOLOGICAL SURVEY

of 41112

PENNSYLVANIA

FOR

1886.

IN FOUR PARTS.

PART I. PITTSBURGH COAL REGION.
PART II. OIL AND GAS REGION.
PART III. ANTHRACITE COAL REGION.
PART IV. MISCELLANEOUS REPORTS.

By the STATE GEOLOGIST.

PART III.

HARRISBURG:

PUBLISHED BY THE BOARD OF COMMISSIONERS
FOR THE GEOLOGICAL SURVEY.
1887.

Entered, for the Commonwealth of Pennsylvania, in the year 1887, according to acts of Congress,

By WILLIAM A. INGHAM,

Secretary of the Board of Commissioners of the Geological Survey, In the office of the Librarian of Congress, at Washington, D. C.

Printed by
EDWIN K. MEYERS, State Printer,
Harrisburg, Pa.

BOARD OF COMMISSIONERS.

His Excellency, JAMES	A. BEAVER, Governor
	and ex-officio President of the Board, Harrisburg.
ARIO PARDEE,	Hazleton.

THIRD REPORT OF PROGRESS

IN THE

ANTHRACITE COAL REGIONS.

BY FRANK A. HILL

CHAPTER I.

The survey of the Anthracite region was commenced as a reconnaisance by Mr. Charles A. Ashburner in August, 1880, and permanently organized by him and under his direction in July, 1881.*

The first report of progress, published in December, 1883, as volume AA, Anthracite Region, Part 1, contains a description of the plan of the survey; a general statement of the work accomplished throughout the Anthracite region; and a detailed description of the eastern end of the southern coal-field, between Mauch Chunk and Tamaqua. The second report of progress, published August, 1886, in the Annual Report for 1885, contains a brief general description of the entire region, and a detailed statement of the work accomplished by the corps from November, 1883, to January, 1886, special reference being made to the results of the survey of the Northern Coal field, between Wilkes Barreand Shickshinny.

In addition to these two reports there was published **June**, 1885, in pamphlet form, statistics of production and **shi**pment of coal from the Anthracite region, for 1883 and 1884, with a general map of the Anthracite coal fields.

[[]Mr. Ashburner's plan of the Anthracite Survey was on my recommendation approved by the Board of Commissioners, and skillfully executed under his direction and personal superintendence, from 1880 to July, 1885; when it became necessary, in view of the preparation of my Summary teport on the Geology of Pennsylvania, to assign to Mr. Ashburner the executive business of the whole State Survey. Thenceforward, under the genral superintendence of Mr. Ashburner, the Anthracite Surveys have been couted, without change of plan, by Mr. Frank A. Hill, who has directed propally all the details of the work of himself and his excellent associates, has prepared this third report of progress.—J. P. L.]

Prior to January. 1887, there were published the following octavo atlases: *

- (1) Atlas, Southern Anthracite Field, Part 1, containing 13 sheets relating more particularly to the Panther Creek Basin.
- (2) Atlas, Western Middle Anthracite Field, Part 1, containing 11 sheets, relating to that portion of the field between Quakake Junction and Mount Carmel.
- (3) Atlas, Northern Anthracite Field, Part 1, containing 13 sheets, relating to the area between Wilkes Barre and Nanticoke; and
- (4) Atlas, Eastern Middle Anthracite Field, Part 1, containing 8 sheets relating to the region surrounding Hazleton and Drifton.

Report A' by Mr. Franklin Platt on the causes, kinds and amount of waste in mining anthracite, published in 1881.

Report AC and atlas on mining methods, etc., in the Anthracite Coal-field, by Dr. H. M. Chance, published in 1883.

It was the original intention to publish reports of progress to accompany each octavo atlas as it appeared, and describe in detail the geology of the district covered by the sheets in each atlas. But it soon appeared that the greatest demand of the citizens interested in the Anthracite mines was for the maps and sections which they could put to immediate practical use, and not for descriptive reports, which would be of more general interest, but of little local utility. Therefore to advance the work as rapidly as possible, the energies of the Survey corps have been almost entirely expended in field work, and in such office work as was necessary for preparing the maps and sections for publication.

Owing to the small appropriation for 1885 and 1886, the size of the corps in the Anthracite region had to be reduced; but, on account of the greater experience of the members of the corps, a larger proportionate amount of work has been accomplished during the past 18 months;

^{*}The sheets contained in these four atlases have also been published in two Common Atlases.

and a number of additional mine, geological and section sheets have been completed, which are described in that part of this report devoted to the special coal-field to which the different sheets relate.

The work of the corps, for the past year and a half, has been confined to finishing up local districts which had already been commenced; so that, while the surveys of large areas have been completed, comparatively little has been done in new areas. During the next two years, the work of the corps will be almost wholly in those parts of the region in which no work has hitherto been done.

In the second report of progress there is given a brief general description of the Anthracite Coal-fields; their geography, history, topography, structural geology, stratigraphical geology and mines. That description will suffice for public use and general reference, until the map work of the entire region has been completed, when it will be again described in greater detail.

Since the publication of the Annual Report for 1885 several maps have been completed and the work on others materially advanced.

The maps which have been completed are as follows:-

A General Map of the Anthracite Coal-fields of Pennsylvania and adjoining counties.

This map shows the position of each colliery and is constructed on a polyconic projection based upon the triangulation determinations of the United States Coast and Geodetic Survey. These locations are so few and scattered that the positions of many prominent points on the map are not geodetically known. The details of the map have been compiled from the surveys of the Geological Survey and of the mining and railroad companies. These surveys are confined almost exclusively to the coal basins outside of which the map has been compiled from railroad surveys and county maps. Although the map may be found by subsequent surveys to be incorrect in many of the details within these latter areas, yet it is the most reliable which can be published at this time. The Geological Survey propose to publish a new and revised map, embracing the anthracite and adjoining areas when its surveys and those of the United States Coast and Geodetic Survey are completed.

This map has been published to meet a want which has long been felt by the several branches of the coal trade and to meet a demand which has been frequently made upon the Geological Survey.

It will be followed by a future publication on which will be shown the position and extent of the several formations below the coal measures in the geological column.

The Lackawanna Topographical Map.

Progress on this map was stopped by the decision of the Legislature at the session of 1885 not to appropriate money for topographical work. The base lines have been completed through the entire area of the field north-east of Scranton and many additional lines surveyed which do not appear on the published sheets (see atlas to this report). These lines are not published be cause they do not complete the topography of any special area. It was the original intention to hold this map until its surveys covered the entire Lackawanna valley north-east of Scranton. It is purposed to publish ultimately a series of sheets (800'=1") of which this survey will be the base, containing in addition to the contour curves of the surface and the land lines, mine workings and data relating to the geological structure of the coal beds.

This unfinished map is now published to meet an urgent demand for the special information which it contains.

Northern Coal-field Mine sheets Nos. I and II.

The completion of these sheets now gives a continuous mapped area from the extreme western end of the Northern coal field to the town of Mill Creek, four miles east of Wilkes Barre. A detailed description of these sheets will be found in Chapter II.

In addition to these maps which have been completed, there are other mine sheets, cross and columnar sections which are nearly ready for publication. The mine sheets, four in number, are all in the Northern coal field in the vicinity of Pittston, Luzerne county. They extend as far east as Spring Brook. It is only necessary to extend the colliery workings of the operating companies to their present boundaries, in order to place these sheets in the hands of the State Printer. In the Northern field we have three unfinished cross sections which extend from the outcrop of the Pottsville Conglomerate, No. XII on the north side of the basin, to the same outcrop on the south side, and several other sections which show the position of the coal beds at individual collieries. We have also sixty columnar sections of the measures cut in shafts, tunnels and bore holes.

Western Middle Coal-field Mine sheets Nos. V, VI, VII and VIII.

The completion of these mine sheets finishes the mapping of the entire area of the Western Middle field with the exception of a small portion which extends north beyond the boundaries of the sheets. A description of these sheets will be found in Chapter III.

In the Western Middle coal field we have six cross sections which will soon be completed and one hundred and twenty columnar sections which only await arrangement on sheets to make them ready for printing.

The necessary work for the completion of these maps, the field and office work on coal statistics (Chapter VII) and the other material contained in the maps and text of this Annual Report for 1886, together with other work in various directions have occupied the anthracite corps during the past year.

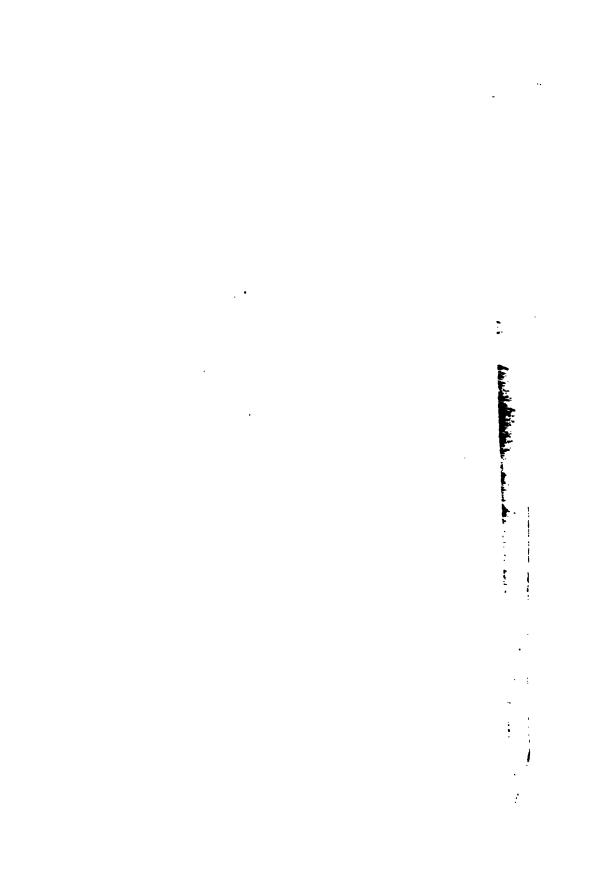

In the Southern field there has been no field work done during the past year, (beyond the collection of data, which would otherwise have been lost) although its importance has been fully appreciated, in view of the great thickness of coal measures in its deeper parts, and because its area is second only in extent to that of the northern field.

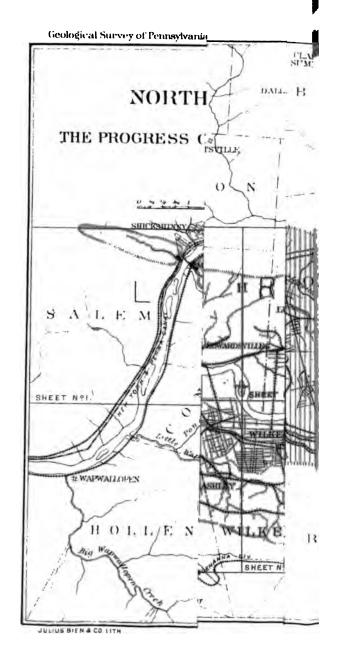

The only series of maps which have been completed in

this field, are those of its eastern end extending from Tamaqua to Mauch Chunk, published in the report of the Panther Creek valley. In default of sufficient appropriations, the survey of the Pottsville basin from Tamaqua westward was suspended. Now, however, the completion of the Western Middle Coal-field mine sheets makes it possible to resume work in the Southern coal field, and complete its survey. Many of the original collieries in this field have been abandoned; most of its early development was done by individual operators; so that a large part of its mining records are scattered through various offices, or held by private persons. These will be collected and used in connection with the new field work of the survey.

In the Eastern Middle or Lehigh coal field, no work has been done during the past year. 'The two mine sheets already published, cover the ground of some of the most important collieries, but a large area is still untouched. It is probable that the whole field will be surveyed and its mine sheets published in the next two years.

The Bernice basin of Sullivan county was mapped and described in the Annual Report for 1885. It remains to define the limit of the adjoining Mehoopany basins in the same field. This work will be facilitated by the use of recent railroad surveys.

CHAPTER II.

Survey of the Northern Coul field.

The survey of the Wyoming or Northern Coal-field by the Geological Survey corps was begun in the latter part of 1881. In May, 1885, the Northern Coal-field Atlas, Part I, was published. This atlas was described in the Annual Report for 1885, and in addition to other material, contained Mine sheets Nos. HI to VIII, inclusive. These sheets cover areas in Luzerne county, which extend north and south, just beyond the limits of the coal field and from the town of Wanamie, in Newport township, Luzerne county, east to the town of Mill Creek, in Plains township, the eastern boundary of Sheet VIII being four miles east of the city of Wilkes Barre.

Mine sheets I and II include within their boundaries the entire width of the coal field and all of its length, west of Wanamie. The eastern edge of Sheet II, is the western edge of Sheet III. The mapped area on these sheets is bounded in a general way, by the outcrop of the bottom of the Pottsville Conglomerate, No. XII.

Mine sheet No. I is the most western of the Northern Coal field sheets. It extends west of Shickshinny, about 2½ miles, far enough to include the extreme western end of the Wyoming or Northern basin. Its eastern line is 5,500 feet north-east of the West End No. I breaker, and crosses the basin nearly at a right angle to the course of its axial line. It embraces within its borders the towns of Shickshinny and Mocanaqua, but outside of these towns its areas are almost uninhabited.

Mine sheet No. II adjoins sheet No. I, and extends east to Wanamie, including the western portion of that town and also the newly-built village of Glen Lyon within its borders.

When in 1881, the survey of the Northern coal field was begun it was intended to publish Mine sheets Nos. I and II with the other sheets in Part I of the Atlas. A little field

work, however, showed the geological difficulties of the area and the desirability of an accurate topographical map as an aid to its development. The Susquehanna Coal Co. through its Chief Engineer, Mr. J. H. Bowden, was at this time commencing work on an accurate and valuable map of that company's property, which has since been finished and placed in the hands of the Geological Survey.

Mining developments were also being made by the West End and Susquehanna Coal Companies, which have since thrown much light on the economic value of their respective properties. These two properties cover the greater portion of both sheets. It was therefore considered best to postpone the survey of these sheets until developments were further advanced, while the Susquehanna Coal Co.'s map was at the same time approaching completion.

After a reconnaisance of several days, on July 1, 1884, the work was begun. The advantage of a topographical map in connection with the study of the geology of this region was at this time even more fully appreciated than before. The Susquehanna Coal Co.'s map and the equally accurate survey of the property of the West End Coal Co. by Mr. Irving A. Stearns, the company's mining engineer, and Mr. H. S. Reets, his successor, were placed in the hands of the Survey and used in connection with the Survey's work in the construction of the present sheets.

The placing of underground workings and the surface contour lines on the same map area has never before been accomplished by the Anthracite Survey over so extended an area. The mine workings on sheets Nos. I and II being comparatively simple, it has been possible to show both these features with little confusion.

Such a showing is very essential in the construction of all colliery maps and its only obstacle should be the confusion arising from the complication of mine workings in several beds underlying each other on the area mapped.

The practical benefits accruing from an accurate map of this kind in development as well as in progressive mining can be readily appreciated.

The fact that these sheets, are, in this particular, repre-

sentative of their class may make a brief mention of the method of their construction of interest and value.

The connecting of the map made by the Susquehanna Coal Company covering that portion of Sheets I and II between Wanamie on the east, and the Dupont and Hassleman drifts of the West End Coal Company on the west; the West End Coal Company's map, reaching from the Hassleman drift to Mocanaqua; and a vernier survey crossing the Susquehanna river and connecting with points on the Salem Coal Company's map, thus joining the West End and Salem Coal Company's properties, made a rigid base to which all the other survey lines were connected. There are 590 points on the two sheets where the survey lines were tied.

The most marked topographical features on these sheets are the mountain slope of the Susquehanna river along their northern borders, and the gap at Mocanaqua made by the river in its sweep to the south, but the many rocky cliffs and spurs, with their attendant hollows, give a variety of contour, which, taken in connection with the study of the coal beds and their intermediate rocks, is of special importance in the location of the outcrops and general geological features.

A glance at the contour curves, which are ten feet vertically apart, will show the abruptness and irregularity of the topography. The rough and broken character of the surface, together with the predominance of the thickly wooded areas, necessitated an amount of detailed work unusual in the construction of maps of this character. The number of stations and length of the lines run per square mile, as shown in the table on page 928, fully illustrates this point.

No section lines at regular intervals were run, but lines along the crests of the hills and bottoms of the hollows, were first established and from these all necessary side lines were extended. Every line was measured by stadia, the rough and wooded character of the country making this method by far the most economical.

One transitman with one, and sometimes two rodmen, worked over a definite area, while a similar party work-

ا، إ

ed over an adjoining area. These working areas were so selected that each transitman checked not only his own work, but the work of his associate. Mr. Arthur Winslow's stadia tables were used in the calculation of horizontal distances and elevations. In the progress of the topographical work the character and dip of the rock exposures were accurately noted.

The following statement will give an approximate idea of the detail necessary in the completion of this work:

<u> </u>
Total length of line in feet
Total length of line in miles
Total number of stations
Total number of square miles contoured 13.02
Average length of line per square mile in miles 21.9
Average number of stations per square mile 438.6
Average length of sight in feet
Average number of stations per day 36.5
Average length of line per day in feet 9,622
Average number of men employed per day 5
Swamp area in acres

After the completion of the topographical field work the mine workings were located on the topographical sheets, being connected by survey points common to both. In this location the mine maps of the Susquehanna, Lehigh and Wilkes Barre, West End and Salem Coal Companies were used, and upon them much of the value of the sheets depends.

Drainage.

The areas embraced by these two sheets are drained by the waters of three distinct creeks and their tributaries. They are: Newport creek, Black creek, and Paddy run. All empty into the North Branch of the Susquehanna river. Of these Newport creek drains the largest area, including almost the entire surface of Sheet No. II. Its drainage system is separated from that of Black creek, by a well-marked water shed, which at its lowest point, is 950 feet above tide, and about 440 feet above the level of the river at Shickshinny. The north branch of

Newport creek is the one of greatest importance. Its source is near the extreme north-western corner of the Susquehanna Coal Company's property, and about 1,600 feet from the line between Conyngham and Newport townships. Its general course is north 70° east. Its waters on Sheet II are fed by those of the middle branch of Newport creek, which, rising in Convugham township, about 300 feet west of the Newport line, flows through the swamp near the Uplinger and Miller farms, and joins the North Branch near the eastern edge of the sheet. In addition to this it receives the waters of two creeks of minor importance from the north slope of the valley, and of one other on its south slope. The south branch of Newport creek, which heads in the swamps near Mackey's clearing, a mile and three-quarters west of Wanamie, flows east through that town and joins the main Newport creek on Sheet III, in the vicinity of Nanticoke.

There is no portion of Mine sheet No. I drained by the branches of Newport creek. It is located entirely on the south-west side of the water shed. As far west as the river. Sheet No. I is drained by the waters of Black creek, which rises in the swamp of that name and flows west, then southwest across the West End Coal Company's property in Conyngham township, and empties into the river a few hundred feet south of the town of Mocanagua. It has but two tributaries and these are of but minor importance; one is the creek which rises about half a mile east of the Dupont drift and which flows into Black creek just north of the Golden drift. The other, Turkey Pond creek, is at times almost dry, but during the Spring rains is a stream of some volume. Some 2,000 feet above its mouth Black creek falls over a high ledge of Pottsville Conglomerate, producing an effect especially interesting in the study of creek erosion.

Paddy run drains the high mountain areas of the Salem basins, and flowing from the west rapidly descends the eastern face of Rocky Mountain and empties its waters into the Pennsylvania canal at the breaker of the Salem Coal Company below Shickshinny. All these streams

have gathered more or less drift, but the rapid fall of Paddy run and Black creek have prevented them from depositing it in quantity along their courses. The main Newport creek, however, with a less rapid flow in a broader valley, has, together with the glacial ice, deposited drift along its course in such quantities that mining beneath it will always have to be preceded by exploration of the drift's depth, before absolute safety can be assured. Similar deposits of drift, but in smaller quantity, are seen along the south branch of Newport creek. The Alden shaft near its southern bank, on Mine sheet No. III, was with difficulty sunk through 68 feet of wash, while in the workings of the Ross Slope, at Wanamie, the south branch of Newport creek was undermined, causing, in 1874, a rush of quicksand into the workings which emphasized in a marked degree the dangers of mining under the drift deposits along these creeks.

The scene of the terrible disaster at Nanticoke of December 18th, 1885, is on Mine sheet No. III, near the banks of Newport creek, and the Buried valley (which is so carefully guarded against by the many borings, made in advance of the workings of the Susquehanna Coal Co.s collieries,) extends west across the line of Sheet II though gradually growing more shallow to the west.*

In this connection the sink holes in the neighborhood of the Uplinger and Miller farms, near the west line of Newport township, are worthy of study. These holes (which are shown on the map) are from 15' to 25' deep, their bottoms and sides being covered with the surface wash from the neighboring fields. How deep the original hole may have been exploration alone will determine. Their presence in a region bearing so plainly the marks of glacial erosion and deposition indicates their origin, while the fact that even after the most violent storms, water immediately drains from them suggests a depth to bed rock which demands precaution and care in the extension of the mine workings beneath them.

^{*}In the Annual Report of the Geological Survey for 1885, pages 627 to 636, Mr. Charles A. Ashburner describes the Buried valley of Newport creek with special reference to the mine accident of December 18th, 1885.

Glacial striæ are found in all portions of these sheets and at all elevations. Their courses differ in direction from south 30 east, to due west. Large pieces of Mauch Chunk red shale are found lying loosely on rocks whose geological position is at least 500' higher than that of the red shale itself. Fragments of this same rock are found on the very highest elevations on the sheet, which are at least 900' above the Susquehanna River level. Large boulders of Pottsville Conglomerate have also been moved by the ice and deposited at various distances from their original location.

Railroads.

There are three separate systems represented in the rail-roads on the sheets. The North and West Branch Division of the Pennsylvania Railroad carries the coal from the West End Breaker No. 1, and also that which it receives at Nanticoke via the Glen Lyon branch from Colliery No. 6 of the Susquehanna Coal Company. The Lackawanna and Bloomsburg Division of the Delaware, Lackawanna and Western railroad receives the Salem Breaker coal, while the coal from the West End Breaker No. 2, and that from Wanamie No. 19, is sent to market over the Lehigh and Susquehanna Division of the Central Railroad of New Jersey.

Each of these railroads have grades most favorable to the direction of their special trade. And under the existing relationship between the operating and carrying companies their locations are especially desirable.

Geology.

The parting between the Mauch Chunk red shale, No. XI, and the Pottsville Conglomerate, No. XII, is clearly defined at all points on the sheets. The Susquehanna, along the north side of the basin, has cut its way down through 600 feet of the rocks of No. XI, dipping $25^{\circ\pm}$ to the south, leaving the massive rocks of No. XII to cap the mountain top. From the eastern edge of Mine sheet II the river continues its western course to Shickshinny where, swinging to the south,

it cuts the coal basin at right angles to its course and exposes the coal measures, conglomerate and red shale in the gap.

On the south side of the basin between Wanamie and. Mocanaqua the dip of the conglomerate is vertical or nearly so along its entire length. These abrupt dips make strongly marked bluffs towering above the eroded red shale valley to the south.

West of Shickshinny and the Susquehanna river the conglomerate-red shale parting is equally well marked, though the red shale outcrop is exposed in a gently dipping mountain slope, instead of steep water cut cliffs as it is to the east. Here, along the summit of the Rocky mountain lie the Salem coal basins a continuation of the main Wyoming basin, but separated from it by the river in its course to the south. The conglomerate outcrop in these basins is plainly seen in the mountain slopes on the north, south and east, while the western end of the conglomerate forms a mountain crest which overlooks the red shale valley beyond.

The horizon locally recognized as the Pottsville Conglomerate, No. XII is that contained between the bottom of the B. Buck Mountain or Red Ash bed and the top of the Mauch Chunk red shale, No. XI. Its thickness on sheets I and II varies from 60 feet in the Salem basins to 140 feet at the Dupont drift. Its average thickness is 110 feet.

About the middle of No. XII, some 60 feet geologically lower than the B bed, on sheets I and II, the A bed is found. While this bed is developed at scattered points through the Northern field it is on Sheet No. I that it reaches its maximum thickness.

Along the south outcrop of the Salem Coal Co.'s counter basin a number of trial shafts have been sunk on the outcrop of this bed. It is also cut in the Mountain tunnel near the west line of the Salem Coal Co's property..

There is a marked thinning of the conglomerate between the south and north sides of the basin, the north side conglomerate with its reduced thickness showing no exposure of the "A" bed.

On the east side of the river in Rope Drill bore hole No.

1, (near Breaker No. 2) of the West End Coal Company, a bed 1'8" thick was cut about 90 feet under the Red Ash bed. In Bore hole No. 2 (900 feet west of the Hassleman drift) what appears to be the same A bed was also cut. At a point north of Black creek and 1700 feet S. 60' E. from the Dupont drift an opening has also been made on what I believe to be the same bed. The opinion is held by some of the parties interested in the properties in this vicinity, that this shafting is on the outcrop of the Red Ash bed. If this latter opinion is correct, it materially increases the value not only of the property in the immediate vicinity, but brings the possibility of finding the Red Ash bed, in the areas separating the several basins, within the limit of probability.

Although the A bed is at no point in the Northern Coalfield considered workable, its occurrence is of geological interest and importance from its probable indentity with one of the (Lykens Valley) coal-beds of the Bernice and Mehoopany basins as well as of the more Southern Anthracite fields.

While the bottom of No. XII is so clearly defined, the outcrop of the B, Buck Mountain or Red Ash bed which marks its top, is in many places so obscure, as to render an absolute conclusion as to its position impossible. The Red Ash being the lowest workable bed, the location of its outcrop outlining the coal area which it underlies, is a matter of great economical importance; while at the same time it defines a prominent geological horizon.

The colliery workings of the Salem basins develop the B bed to such an extent that the location of its outcrop within this area is an established fact.

East of the Susquehanna on the extreme north and extreme south edges of the coal basin, protected by the outcropping conglomerate, the erosion of this coal-bed is simple and its outcrop is preserved; but in the secondary rolls between them, the erosion is so complex that much of the location of this outcrop is theoretical.

As the outcrop of the Red Ash bed defines the limits of

the workable coal beds, its location will necessarily be included in a description of each of the several local basins.

Anticlinals.

The rise and fall of the anticlinals along their axial lines, and the degree of the dips on either side have such a material effect, not only in shaping the outcrops of the several coal-beds, but in determining questions of economical mining, that a brief description of several of the most important may be of value.

Wanamie Quarry anticlinal.

The Wanamie Quarry anticlinal gets its name from its fine exposure in the Ross bed quarry at Colliery No. 19.

The workings in the Baltimore and Ross beds at this colliery outcrop on both sides of this anticlinal, while the Red Ash bed, geologically lower, arches over it before coming to the surface. There can of course be no better determination of the position and dips of an anticlinal than actual mine developments, so that at this point the character of this anticlinal needs no special description.

As we continue west along the axis a north dip of 45° and a south dip of 26° are observed at the eastern edge of the swamp north of Mackeys' clearing. From here west to the West End breaker No. 2, the anticlinal runs through successive swamps, and the rock exposures along its immediate course are consequently few. West of the breaker along the mountain slope the anticlinal is plainly seen, the south dips varying from 5° to 54°, but with an average of about 40°, and the north dips from 4° to 59° averaging about 35°. This anticlinal affects the plan of mining development in this locality separating as it does the Priscilla Lee basin No. 1 from the Newport basin, and the Priscilla Lee basin No. 2 from the Black Creek basin.

A glance at the map will show that while the Red Ash bed outcrops over this anticlinal some 3600' east of the West End No. 2 colliery, and from there west the outcrops on either side are separated by irregular barren areas, yet

south of the Black Creek tunnel on the mountain crest the peculiar effect of the erosion is such that the opposite dips of the Red Ash bed again almost meet on the summit of the anticlinal.

Along this axis near the eastern end of the Priscilla Lee basin No. 2, a number of attendant local axes are shown. While these axes will have some effect upon mining developments, they are entirely local, and have no effect on the general geology of the district.

Mocanaqua-Warrior Run anticlinal.

This anticlinal on Mine sheets III and IV, has already been described in the Annual Report for 1885. On sheet II, while it does not bring the outcrop of the Red Ash bed to day, east of the Teasdale opening, its steep dips will have a very marked effect in shaping the course of future gangways driven in the Newport basin.

At the Halfpenny Barn tunnel at Wanamie, it is attended by a secondary roll through which the tunnel has been driven. This tunnel was driven in confused dips, and any certain identification of the beds or explanation of their relationship to the elevation of this anticlinal, is impossible. Near the Teasdale opening the steep north dips of this anticlinal, form what is locally known as the "Hogback." It is on these north dips that the slope of the West End Coal Company was started, and afterward suspended. West of the Teasdale opening the Pottsville Conglomerate is exposed along the axis of this anticlinal, but with much flatter dips. Just east of the railroad leading to the Golden drift, all trace of the anticlinal is finally lost in the steep dips of the "High rocks."

The third and last of the more important anticlinals is the Newport Centre anticlinal No. I, (the eastern portion of which has already been described in the Annual Report for 1885.) It is clearly shown by surface dips throughout its entire length, and has also been developed by the tunnel workings at Colliery No. 6, Susquehanna Coal Company at Glen Lyon. Its dips are sharp and well defined, and with

the accompanying topography leaves no doubt as to its location.

In addition to the three more prominent anticlinals east of the river, there are the Sand Drift anticlinal in the Black Creek basin; and the Teasdale fault and Dupont Drift anticlinals in the Newport basin, (which have already had a marked effect on the shape of the mine workings of the West End colleries) and the Newport Centre No. 3 anticlinal, in the Newport basin, which is as yet unapproached by mine workings. In addition to these there are numerous anticlinal rolls of local interest.

West of the river, on the Salem side, there are two prominent anticlinals. The most plainly marked is the Salem anticlinal, which forms the northern boundary of the Counter basin. Its south dips will average about 28°, while those on the north vary from 15° to 50°. Towards its extreme western end this anticlinal flattens very rapidly before dying entirely away on the mountain side.

The Paddy Run anticlinal marks the southern boundary of the Crary-Paddy Run basin. It is shown by continuous dips in the hillside, and makes a sharp indentation in the red shale and conglomerate along the mountain top.

Basins.

The separate basins east of the Susquehanna, on the two sheets are the Newport, Black Creek, the Priscilla Lee No. 1, and Priscilla Lee No. 2. All of which are on the south and east side of the river. The basins on the northwest side of the river are collectively known as the Salem basins. They are the Counter, Beadle, No. 4, Spike Island and the Crary-Paddy Run basins.

Newport basin.

The largest and most important of these is the Newport basin, which, rising from under the river flats at Nanticoke, has its western limit at the Dupont drift of the West End Coal Co. This basin is a continuation of the most important one of the Northern coal field, including as it does, not

only the extensive collieries in the vicinity of Nanticoke, Wilkes Barre and further east, but also on Mine sheets Nos. III and IV, the undeveloped areas of the deepest portion of the Wyoming or Northern Coal-field.

The principal development of this basin on sheets I and II is in the No. 6 shaft and tunnel of the Susquehanna Coal Co., the Hasselman (Colliery No. 2), and Dupont (Colliery No. 1), drifts of the West End Coal Co., and the Wanamie No. 19 colliery workings of the Lehigh and Wilkes Barre Coal Co. Just east of Mine sheet No. II, on Sheet No. III, are the extensive workings of the Susquehanna Coal Co., at Nanticoke. These workings have now so thoroughly developed the coal beds in this locality, that the conditions and characteristics of the coal measures in the immediate vicinity are very thoroughly understood. The basins and saddles which these workings develop together with those further to the south continue west on Sheets II and I.

At the No. 1 shaft, of the Susquehanna Coal Co., west of Nanticoke, (on Mine sheet No. III), the Red Ash bed is cut at an elevation of 400 feet below tide. The outcrop of this bed at the Dupont drift, which is at the extreme western limit of the Newport basin, is 750 feet above tide. rise from Shaft No. 1 towards the west is therefore 1.150 feet in a distance of about 6 miles. In the No. 1 shaft 9 workable beds are cut, the highest being 473 feet above These beds therefore outcrop between No. 1 shaft and Dupont drift. It will be observed, however, that the Dupont drift is not in the same local basin as the No. 1 shaft, but develops a basin more to the south. The basin in which Shaft No. 1 was sunk dies away in its rise to the west along the mountain slope north-east of the Dupont drift.

The best development of the coal measures on sheets Nos. I and II are those at the Susquehanna Coal Company's No. 6 colliery at Glen Lyon. The shaft which is 749 feet deep, cuts 7 workable coal beds, all of which must outcrop On sheet II, between No. 6 shaft and the Dupont drift.

There are no bore holes (other than those used for test-

ing the depth of the surface wash), or other trial holes on the sheets within the limits of this basin.

The outcrops, however, of the several coal beds have been proven in many places on the properties of the different companies.

Probably the most profitable bed mined on the area covered by these sheets is the Red Ash, the location of the outcrop of that portion bounding the Newport basin is herein described.

The shaft and tunnel at the No. 6 colliery have extensive workings in the beds which are cut by them. The following sections taken at various places in the workings will show the character of the coals mined.

Section of Ross bed taken in East gangway of tunnel workings 350 feet from tunnel:

			T	ota	al.		 										-	110" 9"

The workings of the Wanamie No. 19 Colliery develop an anticlinal and basin, the latter of which continues west to the end of the Wilkes Barre mountain. This basin is known as the Priscilla Lee and while it is really a southern

This model brings out strongly to view the sigmoid water-shed between Mocanaqua and Wanamie, the highest point of which is 1140' A. T.; the lowest 910' A. T. or 410 feet above river level at Mocanaqua; Newport creek waters draining east, and Black creek waters west from it.

The large arrows on the model indicate the direction of the glacial scratches observed by Professor Branner; and others observed by Mr. Lehman, along the North and West Branch railroad, on red shale exposures at the base of the hill, parallel with the river; showing that the last ice flowed down the river bed westward.

The accompanying heliotype plate represents the modeled surface of the western end of the Northern Anthracite coal field, made by Mr. George M. Lehman, of the Survey, from Mine sheets Nos. 1 and 2; each contour line being cut out of cardboard, $\frac{1}{4^{10}}$ of an inch thick, to represent 20 feet of vertical height. The vertical and horizontal scales being the same [800':1"] there is no distortion. A heavy line, following the outcrop of the Red Ash [Buck Mountain] coal bed, marks the productive coal areas, seven in number; four of them on the western side of the river. The dotted line represents the contact of the Mauch Chunk red shale with the bottom of the Pottsville conglomerate. The steep dips along the southern edge of the field brings these two lines closer together than along the northern edge. The highest elevation of the northern outcrop of conglomerate is 1420 A. T.; at the western end of the Salem basin 1350 A. T. or 840' above the river. The slope to the river is everywhere along this ridge about 45°. In five miles the river surface level only falls ten feet.

This model brings out strongly to view the sigmoid water-shed between

	·	
	·	

spur of the Newport basin it is generally considered as a separate one, and shall be so spoken of here.

Beginning at the eastern edge of Sheet No. II near its south-eastern corner we can readily trace the Red Ash outcrop towards the west, along the south side of this basin. Along the north side of the Priscilla Lee basin No. 1 and separating it from the Newport basin is the Wanamie Quarry anticlinal. In the vicinity of Wanamie we find that the north dips of the Red Ash bed in the Newport basin proper do not rise to the surface, but turn over the Wanamie Quarry anticlinal into the Priscilla Lee No. 1 basin, just mentioned. The Red Ash b-d arches over this anticlinal below the surface until it reaches the vicinity of the West End Colliery No. 2, where the erosion which has exposed the rocks of No. XII along the anticlinal has also stripped the overlying outcrop of the Red Ash bed. from this point the anticlinal in the Conglomerate, rises along the mountain side, the Red Ash along its southern dips forming the north outcrop of the Priscilla Lee No. 1 basin, while on its north side following it to the west we find the outcrop shown in the Hassleman, James, and Teasdale openings under the high cliffs which are seen north and east of Black Creek and the Turkey pond.

Leaving the Teasdale opening we can still follow the outcrop to the west by the topography between this opening and the Turkey pond creek and by the exposure of No. XII in this locality. Continuing west of Turkey pond creek between it and the Dupont drift, (while there is no shafting on the outcrop) the rock exposures would indicate the position of the Red Ash bed as shown on the sheets.

After reaching the Dupont drift (the workings of which on this bed are very extensive) the crop is shown irregularly eroded along the hillside reaching north towards the crest of the river mountain. Continuing east along the mountain, the outcrop can be traced by the existing topography to the eastern line of the West End Coal Company's property. At or near this point the bed seems to separate forming two distinct splits, and these two splits are developed in continuous shaftings across the property

of the Susquehanna Coal Company as far east as the wagon road, crossing the river mountain, from the County Poor house into the valley of Newport creek. From here east to the sheet line, though broken by anticlinal rolls, the outcrop is partially indicated by occasional exposures in the creek beds, but on the north-eastern side of the Newport Creek anticlinal No. 3 its location is very uncertain.

At Nanticoke as well as at other points through the Wyoming basin, these two splits of the bottom bed occur.

The existence of a bed beneath the one known as the Red Ash at the mouth of the Dupont drift is proven improbable by the Diamond drill bore hole which was bored at the drift mouth from the bottom of the Red Ash bed into the red shale, a distance of 192' without encountering the slightest evidence of coal. The following section shows the thickness and character of the rocks encountered in this hole.

Section of Diamond Drill bore hole No. 1 at the mouth of the Dupont drift of the West End Coal Company, in the Newport basin.

The No. 6 colliery of the Susquehanna Coal Co., which is one of the largest in the northern coal field, is opened by a shaft, tunnel and slope. The surface plant has probably no superior in the anthracite region. The breaker has a probable capacity of 2000 tons per day, and is filled with the most modern appliances known in the preparation of coal.

During the past year a town of over one thousand inhabitants has sprung up in the vicinity of this mine. Everything points to the permanency of the town's rapid growth, and the probability of a large production from the colliery.

Adjoining the Susquehanna Coal Co.'s property on the east is that of the Lehigh and Wilkes Barre Coal Co. These lands extend across the coal field and include the entire width of the Newport basin. There are no mining developments on this property other than those along the extreme southern outcrop at the Wanamie colleries. But, as the basin rises from the east towards Glen Lyon all the coal beds cut in the Susquehanna Coal Co.'s No. 6 shaft will be found on the Lehigh and Wilkes Barre tract, while on its eastern boundary one or possibly two additional beds will outcrop.

Adjoining the Susquehanna Coal Co.'s property on the west are the lands operated by the West End Coal Co.

This property includes within its borders the western end of the Newport and Priscilla Lee No. 1 basins and all of the Black Creek and Priscilla Lee No. 2 basins. So that while in the matter of ownership there are several interests involved in the Newport and Priscilla Lee No. 1 basins, the characters and conditions of the coal beds of the Priscilla Lee No. 2 and Black Creek basins in a commercial sense only directly effect those interested in the West End Property.

This company is working the Dupont drift in the Newport basin, the largest portion of their mine production coming from this opening. These workings have now extended eastward to within several hundred feet of the old Dr. James house now occupied by Mr. Lem. Uplinger.

The Dupont drift mines the Red Ash bed, an average section of which is as follows:

The West End Breaker No. 2, which prepares the Hasselman coal for market, is at present idle, waiting the progress of the gangways from the inside slope of the Dupont drift to develop the Newport basin to the north.

The Teasdale opening which is supposed to be on the

same bed as the Hasselman opening, was originally opened by drift, and from it a slope was started which was expected to be driven to the bottom of the basin. Owing to the steep irregular dips which it encountered it has been for the present suspended, until the gangways from the Dupont drift shall have advanced sufficiently to the east to render possible the driving of a slope up from below to meet the already opened Teasdale slope.

In addition to the colliery workings in this basin already noted, there are several openings the workings of which are of limited extent. The most notable instances of this kind are the drift at Mackey's clearing 1\frac{1}{4} miles west of Wanamie and the Shoemaker drifts, east of Glen Lyon. No map records of the workings of these smaller openings have been preserved. The following sections show the character of the coal-beds at the Shoemaker drifts.

Priscilla Lee basin No. 1.

The Priscilla Lee basin No. 1, which has been before mentioned in connection with the outcrop of the Red Ash bed, is one which has not as yet been extensively mined. It is a southern spur of the Newport basin, the coal measures of which are not separated from it. On the eastern border of sheet No. II, in the workings of the Wanamie No. 19 colliery, the Baltimore, Ross and Red Ash beds have been developed.

At the No. 2 colliery of the West End Coal Company, a tunnel has been driven in this basin which cuts five beds. The colliery workings, however, at the latter tunnel have not been extended either east or west of the tunnel, except in the case of the 2d bed, 240 feet from the tunnel mouth. A gangway on this bed has been driven 325 feet west.

About 1200 feet south of the Hasselman drift and 200 feet west from the above mentioned tunnel, Diamond Drill bore hole No. 3 was sunk which also cuts 5 beds on the opposite south dip. The appended sections of the beds cut in No. 3 bore hole will serve to show the character and condition of the beds in this immediate locality.

· · · · · · · · · · · · · · · · · · ·			_			_								

The structure of this basin from Wanamie to a point about 4000 feet west of the West End No. 2 tunnel seems comparatively simple as the outcrop protected by the steep north dipping conglomerate remains undisturbed, but from

this point west to the end of the basin, the dips are sufficiently complicated to produce many difficulties in min-It will be observed that at the end of this basin a complete break in its continuity is shown. This interpretation is disputed by local maps. The fact that a basin in the Red Ash bed and overlying measures rises to day in the hollow at this point is patent to any one who has been on the ground. In the hollow the south outcrop is completely eroded and the rocks exposed in the hillside have a clearly defined south dip of about 28 degrees. These south dips continue west along the hillside for about 1200 feet where they are superceded by an opposite dip of 65 degrees. The crest of the anticlinal immediately North of the exposed basin in the hillside is concealed. It shows east and west of this point along the cliff for several hundred feet before being lost in the north dipping rocks of the second or more western basin.

In order to make a proper distinction we have called the eastern basin Priscilla Lee No. 1 and the western and smaller basin Priscilla Lee No. 2.

The point in question is whether the Red Ash bed outcrops on the south side of this anticlinal or whether it folds over before reaching the surface. If the latter view is correct the coal extending from the West End No. 2 colliery to the western end of the Wilkes-Barre mountain may possibly all be mined from the tunnel at that colliery without driving additional inside tunnels, but if the former, such working will be absolutely impossible.

The survey considers the outcrop line as indicated on the sheets by far the more probable structure.

As has before been stated, the Priscilla Lee basin No. 1 as a distinctive basin has its most western development in the workings of the Wanamie collieries of the Lehigh and Wilkes Barre Coal Co. The anticlinal which separates this basin from that next basin to the north is distinctly shown in the colliery workings of the Baltimore and Ross beds at Colliery No. 19. Shaftings have been made on both dips of the basin at various points along its course to the west.

The Pottsville conglomerate underlying this basin is not

exposed until it reaches the extreme western end of the mountain overlooking the Shickshinny gap.

At the West End No. 2 colliery the conglomerate is exposed on the axis of the Wanamie Quarry anticlinal between Hasselman's opening and the south dipping outcrop of the Priscilla Lee basin. At this point the colliery developments, together with records of the Diamond Drill bore holes of the West End Coal Company, clearly define the outcrop of the Red Ash bed except near the point where it crosses the anticlinal axis. From here to the west the Red Ash is not shafted but is shown in a very clearly defined terrace for a distance of 3000 feet, at which point the dips become so confused that no definite location of the outcrop is possible.

Whether the coal beds along the south outcrop of the basins, with their almost perpendicular dips, will retain the thickness and condition found in the flatter dipping measures to the north, can only be discovered as mining operations progress.

The section of the Diamond Drill Bore-hole No. 3 is an actual proving of the character and position of the coal beds and their intermediate strata in the Priscilla Lee Basin No. 1 in the vicinity of the West End Colliery No. 2.

Priscilla Lee basin No. 2.

The Priscilla Lee basin No. 2, which extends from a point 500' west of the most western exposure of the Priscilla Lee basin No. 1, to the western end of the Wilkes Barre mountain, is entirely undeveloped. The only coal shafting within its borders is near the axis of the Wanamie Quarry anticlinal on the mountain crest at a point 1100' south of the Black Creek tunnel.

The south outcrop of the Red Ash bed in this basin, while not opened, is clearly defined by the surface topog-

raphy in connection with the north dipping conglomerate. This outcrop which so plainly shows on the south side of the basin can be followed around the basin's western end and thence along the northern outcrop to the south dipping rocks in the coal shaft which has already been mentioned.

In tracing the outcrop of this basin from here to the east its identity is lost in the confused dips existing along its north edge, while the exact definition of its eastern boundary is impracticable. The local rolls and confusion of dips noted on these sheets along the crest of the mountain will plainly show the difficulties of reaching a definite conclusion as to the outcrop of the coal beds. Over a large part of this area including its southern and western portion the dips are very regular but the extreme northeastern part of the basin is broken by irregular dips in all directions. this basin is an isolated one, and every indication seems to prove that such is the fact, it will be one difficult to mine from the fact of its isolation as well as from its position on the summit of the mountain. A succession of shaftings would throw much light on the position and number of the coal beds in this and the Priscilla Lee No. 1 basins, both of which are now concealed in the confusion of the many dips. The area of workable coal in this basin is 67.87 acres.

Black Creek basin.

The Black Creek basin is about 6600 feet long and extends from the West End No. 1 breaker to the sharp northwest bend in Black Creek 1600 feet south of the Dupont drift. Its principle mine openings are the Conyngham and Mud drifts and the Black Creek tunnel on the Red Ash bed; the Golden drift on the Ross bed and the "Church" drift on the Church bed. The Mud drift which was opened within a few feet of the lowest point of the outcrop of the Red Ash bed, in the western end of the basin, is at present the most important opening. Its gangways are driven of the north and south dips and as they extend east the distance between them gradually increases.

500 feet from the mouth of the drift they are 100 fee * =

apart, while at the present face of the gangways they are separated by a distance of 1100 feet. An average section of the bed in this drift is:—

The breasts on the more southern gangway of the Mud drift develop the anticlinal upon which the air shaft was sunk. The northern gangway developed the south dip which has an unbroken rise to its outcrop above the Pottsville conglomerate capping the hill overlooking the river.

Until recently it was supposed that the bed worked in the Mud drift was identical with that worked in the Conyngham drift and in the Black Creek tunnel. While endeavoring to connect the Mud and Conyngham drifts the fact was developed that they were on separate beds. A tunnel has been driven south from the Mud drift into the Conyngham drift and another north from the south dip gangway of the Mud drift into the south dipping bed corresponding to that worked in the Conyngham drift. This latter bed along the north dip was cut in fault, but gangways are now being pushed eastward, which will probably develop this bed in its normal condition.

The Black Creek tunnel, 40 feet in length, cuts the north dipping crop of the Red Ash bed as it rises in the north slope of the Wilkes Barre mountain.

The mining operations at this tunnel are at present suspended. The Diamond Drill Bore hole No. 4, of the West End Coal Co. (a record of which follows below) was sunk from the bottom of the Red Ash bed at the face of the tunnel. It was drilled at an angle of 83 degrees with the pitch for a depth of 110' without cutting any coal.

Section of Bore Hole No. 4 in Black Creek Drift, Black Creek Basin, Starting on bottom of Black Creek bed. West End Coal Co.'s Pitch of Bore Hole 66% south. Dip of measures 30° north.

There are 243.30 acres of workable coal in the Black creek basin, all of which is controlled by the West End Coal Company. The worked areas are as follows:

Red	Ash	Bed	, Upper	split,	Mud drift, 12.63 acre	8.
"	44	"	Lower	66	Conyngham drift, 6.61 "	
44	66	"	66	"	Black Creek tunnel, 3.67 "	
Ross	Be	d Go	lden Dri	ft, .	4.26 "	
Chu	reh.					

The coal measures of the Black Creek basin are isolated from those of the other basins.

The outcrop of the Red Ash bed as has already been

noted is developed by the mine workings of the Mud drift, Conyugham drift and the Black creek tunnel. is shown by their workings from a point northeast of the West End No. 1 breaker, near where the south dip airway from the Mud drift has been driven to day, west along its northern outcrop, then south along the extreme western exposure of the basin overlooking the river, then east along its south dip to the Black Creek tunnel where it is seen plainly rising along the north slope of the mountain until nearing the crest it turns to the southwest, then sharply to the east a distance of 800' and again follows north down the mountain side until it reaches the plainly marked hollow east of the mouth of the Black Creek tunnel. Following this hollow until Black creek is reached, it runs along the south bank of the creek until at a point near the Golden drift on the Ross bed it crosses the creek and is lost in the steep dipping measures at the foot of the high cliff which is such a prominent feature in the topography of this basin.

From here west to our starting point near the airhole the broken character of the outcropping rocks and the confusion of their dips make the location of the outcrop very uncertain.

The north dips of the Black Creek basin are, as far as can be seen from the surface indications, very regular. The same is true of the south dips on the north side of the basin for a distance of about 1 mile from its western end. Here the dips become steeper and somewhat confused while opposite the high cliff west of the Dupont drift they become so irregular that all indication as to the position of the coal bed is lost.

Salem basins.

On the west side of the Susquehanna, separated by the river gap from those more directly a part of the Wyoming basin, are the Salem basins. These basins are the extreme western continuation of the intermediate basins of the Wyoming or Northern coal-field and extend from the eastern face of Rocky mountain overlooking the river to

about two miles west. The Pottsville Conglomerate underlying them outcrops on the north and south side of the mountain and its minor rolls bring the outcrop of the Red Ash bed to day-light, forming several local basins. The bottom of the conglomerate, however, at no point reaches the surface within the areas thus made barren of coal. These local basins surrounded by the Red Ash crop are the Beadle or Counter basin, the No. 4 basin, Spike Island basin and the Paddy Run-Crary basin.

The Red Ash bed in all of them has been thoroughly mined and robbed.

The most important basin both in extent and production is the Counter, which also includes what is known as the Beadle basin.

The Counter basin is two miles in length and in addition to the Red Ash bed which, through the Salem basins is known as the B or Buck mountain, includes limited areas of the Ross or C and a small bed still higher known as the D bed. The A bed is not workable though its thickness as developed in this basin (which has before been noted) is exceptionally great.

An average section of the B bed in the Counter basin shows:

Top.																
Coal, .													1′	. 10′′		
Slate,																.6'
Bone,																.6"
Slate,																.8"
Coal, .													4′	.2"		
Bottom.													-			
		7	Го	ta	le.								6′	.0′′	1′	.8"

It is impossible to enter the workings of these basins, many portions of which have been closed for years. No description other than that shown by the map of the workings is therefore practicable. The course of the mine workings will be noted as indicating a number of local synclinals and anticlinals.

The C and D beds have been shafted at various points but have never been worked. The thicknesses reported by the company as shown in these shaftings is as follows:

C. Bed. About 700' northeast of tunnel.
Top coal,
Slate,
Bottom coal,
C. Bed. About 700' northwest of tunnel.
Coal bed, \dots 6' .4"
D. Bed. Near center of basin south side.
Coal,
D. Bed. Near western end of basin, north side.
Coal,
A. Bed. Where cut in tunnel.
Top, sandstone.
Coal,
Slate and coal,
D. Bed. Near center of basin north side.
Coal,
There is no irregularity in the dips of the Counter basin
worthy of note

n worthy of note.

The Spike Island basin, the smallest of the Salem basins is entirely mined out and has been closed for some years.

The same is true of the Paddy Run-Crary basin. basin is broken by a very sharply overturned anticlinal. The fact of the mine workings being completely closed renders it impossible to make any examination of this overturn.

The Salem Coal Co. own the entire area of the Salem basins, with the exception of a small portion at the extreme western end of the Counter basin. The following statement will show the acreage of each local basin.

Geological Survey of Pennsylvan ch of Rog LITTLE MAHANOY WESTE MINE CH BERGEATZ 393.

CHAPTER III.

Survey of the Western Middle coal field.

The mine sheets of the Western Middle Coal Field, as constructed by the Geological Survey, are similar in character to those which have already been described in report AA and in the Annual Report of 1885.

In the latter report there was given a brief reference and description of the mine and cross section sheets, which had been finished up to that time. These sheets were published in the Western Middle Coal Field Atlas, Part 1. They are 11 in number, as follows:

Four Mine and Geological sheets, scale 800 feet to 1 inch, 5000 of nature showing the plan of all the mines and the shape of the floor of the Mammoth Bed, where mined, and its most probable structure in undeveloped areas, by contour curve lines, 50 feet vertically apart.

- 1. No. I, Delano sheet, between Delano and Mahanoy City, in Schuylkill county.
- 2. No. II, Shenandoah sheet, between Mahanoy City, Shenandoah, and Gilberton, in Schuylkill county.
- 3. No. III, Girardville sheet, in vicinity of Frackville and Girardville, in Schuylkill and Columbia counties.
- 4. No. IV, Ashland sheet, in vicinity of Ashland, Locust Dale, Centralia and Montana, in Schuylkill, Columbia and Northumberland counties.

Three Topographical sheets, scale 1600 feet to one inch, 15200 of nature, showing the topography of the surface by contour curve lines 10 feet vertically apart.

- 5. No. I, Mahanoy City and Delano sheet, in the vicinity of Quakake Junction, Delano and Mahanoy City, in Schuylkill county; embraces the area on Mine sheet No. I.
- 6. No. II, Shenandoah and Girardville sheet, in the vicinity of Mahanoy City, Shenandoah, Frackville and Girardville in Schuylkill and Columbia counties; embraces area on Mine sheets Nos. II and III.

7. No. III, Ashland and Mt. Carmel sheet, in the vicinity of Ashland, Locust Dale, Centralia, Montana and Mt. Carmel, in Schuylkill, Columbia and Northumberland counties; embraces area on Mine sheet Nos. IV and V.

Four Cross Section sheets, containing vertical cross sections exhibiting the geological structure of the coal-beds. Scale of sections, 400 feet to 1 inch, T_{Rho} of nature.

- 8. No. I sheet contains 4 sections between East Mahanoy tunnel and Mahanoy City.
- 9. No. II sheet contains 5 sections between Mahanoy City and Mahanoy Plane.
- 10. No. III sheet contains 4 sections between Mahanoy Plane and Girardville.
- 11. No. IV sheet contains 2 detail and 11 skeleton sections between East Mahanoy tunnel and Locust Dale.

Mine sheet No. I was commenced in November 1881, and Nos. I, II, III and IV, finally printed in October, 1883. No. V was printed December, 1886, while VI, VII and VIII are still in the hands of the state printer. They are all based on the maps and surveys of the coal operating companies in combination with those of the Geological Survey.

In August and September, 1881, Prof. C. L. Doolittle determined the longitude and latitude of the court houses in Pottsville, Schnylkill county, and Wilkes Barre, Luzerne county, and established the true meridan in each locality. This meridan was carried by a survey made by the Geological Survey corps from the geodetic point at Pottsville, to what is known as the Gilberton tangent on the Philadelphia and Reading railroad and from this tangent, throughout the field. From this survey the true meridan and a rigid base for the Western Middle sheets was established.

In their construction the colliery maps of the operating companies, and individuals were connected by the survey with the base map and these together with information obtained from various sources, were added until the sheets were completed. The Philadelphia and Reading Coal and Iron Company, controlling by far the greatest proportion of the territory embraced by these mine sheets, have in their

possession connected maps on a scale of 300 feet to the inch, showing all their properties. This scale was adopted by the survey in the construction of their "working sheets," as saving the labor and time which would have been necessary in the reduction of the Coal and Iron Company's maps to a different scale. The maps of the other companies and of individuals which were placed in the hands of the survey, were in different stages of completion and made on a great variety of scales. These were all reduced to the scale of the base map (300 feet to 1 inch) and added to it.

It required a great amount of field work by the Geological Survey corps to establish a proper connection between the base map and the mine maps and surveys of the operators. In addition to this, many surveys and examinations were necessary to determine outcrops and establish certain geological conclusions in the construction of the sheets. These surveys included not only surface examination, but also a great amount of detailed underground work.

After the completion of the sheets on the scale of 300' to one inch, they were sent to the engraver and there reduced to the scale of 800 feet per inch, on which scale they were finally printed. They show the property lines, streams, railroads, wagon roads, town plots, colliery buildings and other surface features, also the horizontal projection of all the mine workings in the coal-beds of the several collieries, together with contour lines drawn 50 feet vertically apart on the floor of the bottom member of the Mammoth bed, showing its actual position in worked areas, and also its most probable structure in the areas which have been undeveloped.

Since the publication of the Annual Report for 1885, the field and office work on 4 additional mine and geological sheets Nos. V, VI, VII and VIII have been completed. They are as follows:

No. V. Mt. Carmel sheet extending from the county line between Columbia and Northumberland counties, east of Mt. Carmel, to about 17000 feet west of that town.

No. VI. Shamokin sheet extending from 17000 feet west

from the town of Mt. Carmel to Shamokin, Northumberland county.

No. VII. Bear Valley sheet, extending from Shamokin, Northumberland county, west for 23000 feet.

No. VIII. Trevorton sheet joins sheet No. VII on the west, and extends to about 10000 feet west of Trevorton gap.

Of these, the edition of No. V has been printed. The others are at present in the hands of the printer, and will soon be ready for distribution. In addition to these 4 geological sheets, 7 additional cross sections exhibiting the geological structure of the coal-beds have been made. These, together with the sheets containing columnar sections of the coal measures cut in shafts, tunnels and bore holes, together with those compiled from actual colliery workings and surface exposures, within the area embraced by the mine and geological sheets will form Part II of the Atlas.

The Western Middle Coal-field Atlas, Part I, was incomplete from the fact that it contained no columnar section sheets exhibiting the position and character of the coal-beds or of the rocks between them. The columnar section sheets which will be contained in part II of the Atlas, will include not only columnar sections embraced by Mine sheet Nos. V, VI, VII, VIII, but also those within the areas embraced by sheets I, II, III, and IV, and the general plan used in representing the topographical, geological and mining features on these sheets is the same as that already shown on those to the east with the exception of the conventional used in representing colliery gangways, airways and breasts. These on sheets V, VI, VII and VIII are shown in the same detail as on the working maps of the operating companies.

Drainage.

The surface drainage of the Western Middle Field is very simple. Pine creek drains quite a limited coal measure area in the vicinity of Delano, Schuylkill county. This creek empties into the Little Schuylkill, two-and-a-half

miles above the town of Tamagua. With this one exception, the area of the Western Middle Coal Field is drained by the Mahanov and Shamokin creeks into the Susquehanna river. The Mahanov creek rises 2000 feet, more or less, south of the town of Delano, and flows east until it reaches the town of Ashland. Its course is through the Mahanoy basin proper, its feeders coming in from the adjoining local basins to the north. At Ashland this creek breaks through the Mahanoy mountain, and from this gap west to the Susquehanna river, flows through the Mauch Chunk red shale and underlying rocks. East of Ashland its tributaries rise and flow almost entirely within the coal meas-They include the north branch of Mahanov creek, Waste House run, Shenandoah creek, and Big Mine run. West of Ashland the only coal measure stream, the waters of which reach the Mahanoy creek, is that of Big run. This, like the main creek itself, breaks through the Mahanoy mountain and both unite in the red shale valley to the south. West of Ashland, with the exception of Big run, the drainage of the coal basin is towards the west. Excepting a very small portion of the basin in the vicinity of Treverton, the water of all the streams finds its way into Shamokin creek. The main branch of Shamokin creek has its source just west of the town of Centralia. It flows east through Mount Carmel and Shamokin, breaks through the Cameron Gap north of the latter town, and from here flows through strata under-lying the coal measures and empties into the Susquehanna at Sunbury. The extreme western portion of the coal field is drained by Zerbe's run which breaks north through the Big mountain and continuing its course west through the Mauch Chunk red shale enters the Mahanov creek near Hunter's Station, in Northumberland There are three well marked water sheds within this area. One near Centralia, Columbia county, the eastern slope of which is drained by Big Mine run, and the western slope by the middle branch of the Shamokin creek. Another east of Locust Summit, the eastern slope of which is drained by the waters of Big Mine run, and the western slope by the Locust creek. The third, and least important

of these water sheds, is that which separates the waters of Zerbe's run from those of Carbon run which flow east into the Shamokin creek.

Although producing very heavy grades none of these water shed summits are of sufficient height to prevent their being crossed by the various railroad systems of the basin. The railroad grades are therefore very often adverse to trade, while the different railroad systems, in many portions of the field, are not separated by the topographical features of the region but are seen climbing the summits in almost parellel lines. The eastern boundary of Sheet 1 is a quarter of a mile east of the town of Delano, Schuylkill county. From this point the sheets extend westward for the entire length of the basin. The western edge of Mine sheet No. VIII being 2 miles west of Treverton, Northumberland county. The sheets have been so arranged that their north and south borders are continuous straight lines including the greatest coal area possible.

Within this area there have been developed sixteen separate workable coal beds. The following list will show their geological order and their local naming:

Little Tracy Bed No. xvii.

Big Tracy Bed No. xvi.

Little Diamond Bed No. xv.

Diamond Bed No. xiv.

Little Orchard Bed No. xiii.

Orchard Bed No. xii.

Primrose Bed No. xi.

Holmes Bed No. x.

Top Split Mammoth Bed No. ix.

Middle Split Mammoth Bed.

Bottom Split Mammoth Bed No. viii.

Skidmore Bed No. vii.

Seven Foot Bed No. vi.

Buck Mountain Bed No. v.

Upper Lykens Valley Bed.

Lower Lykens Valley Bed.

The characteristics of these beds are so varied in different parts of the field that it is difficult to define their thickness and relationship in a general way. A detailed knowledge of the individual beds however may be obtained by a study of the mine and section sheets.

East of Delano a very small portion of the Mahanoy basin extends beyond the boundaries of the sheet. It includes limited areas of the Buck Mountain and Lykens Valley coal beds. The eastern limit of the former bed is within a few hundred feet of the sheet line, while the outcrop of the Lykens Valley bed extends for a distance of a mile beyond the border of Sheet No. I.

On the south side of Sheets Nos. I and II is the New Boston basin which extends south beyond the limits of As much of this basin however, as is inthose sheets. cluded on the sheets has been carefully mapped. mainder will be published on future sheets to the south which will include the coal measures of this and other basins along the Broad Mountain. On the north sides of sheets II, III, IV, V, VI, and VII the coal measures extend at various points beyond the limits of the sheets. The sheet line in some places cutting through the workings of important collieries. The workings of these collieries have all been carefully mapped to the edge of the sheet. Their remaining portions will be mapped when a new series of sheets, north of the present ones, shall have been completed. West of the western edge of sheet No. VIII there extends an area underlaid by the Lykens Valley bed. has been mapped on a portion of Mine sheet VIII, and has also its connection with the rest of the basin shown.

There are four distinct outcrops on these sheets which the Survey has attempted to especially define, they are; the parting between the Mauch Chunk red shale, No. XI and the Pottsville conglomerate, No. XII; the outcrop of the Lykens Valley bed (the lowest coal bed in the series); the outcrop of the Buck Mountain bed which is underlaid by "the Buck Mountain rock," a large egg conglomerate, which is locally considered a key rock in the study of geology of these and neighboring basins; and lastly the outcrop of the Mammoth bed. The parting between No. XI and No. XII is clearly shown at all points

on the sheets, either by its actual exposure or by the topographical features which in this section of the State always accompany it.

The outcrop of the Lykens Valley bed has been located at all points excepting along the main ridge of the anticlinal just north of Centralia, Columbia Co., where it was impossible to obtain sufficient data to warrant the location of this outcrop with any assumption of accuracy.

The location of the Buck Mountain bed is shown on all the sheets except in the vicinity of Raven Run northeast of Girardville, Schuylkill county. At this point, owing to the confusion of underground dips and the lack of surface indications, an accurate location of this outcrop was impossible.

The Mammoth bed outcrop was located largely by actual developments in the colliery workings.

Of the three coal beds whose outcrops are specially defined the Lykens Valley is the one least worked. There are four collieries in this field, which have been dependent upon the Lykens Valley coal bed for their production, namely: The Helfenstein, Ben Franklin, Gordon and North Franklin collieries. Aside from these workings and a few small drifts in the vicinity of Montana, Columbia County, the outcrop of this bed has been proven only in trial shafts scattered along the entire length of the basin. This bed. however, occurring as it does in the hard unvielding measures of the Pottsville conglomerate, while often not showing the slightest exposure, can almost always be approximately located by the occurrence of the conglomerate cliff, which its outcrop generally occupies.

The Buck Mountain bed has been more or less extensively worked on each of the sheets. In addition to this it has been trial shafted in many places, and resting on so marked a horizon as the Buck Mountain rock, its position is readily recognized.

The most extensive mine workings on the sheet are those in the Mammoth coal bed, these of course locate the outcrop of the Mammoth wherever worked. While in the undeveloped portions trial shafts and surface indications have

been used in defining the outcrop and structure of the bed, much time and labor was spent in contouring its floor. The study of this structure required the collection of much data and the compilation of the same after its collection. The Mammoth bed, which is the one most sought for by mining prospectors and the one most extensively worked, was especially chosen to illustrate the structure and local features of the basin, because it is the most important bed in the series. This is eminently true in a commercial sense, but in addition to its well recognized features, which make its identity comparatively easy, the extent of its mining and its geological position gives it an importance which demands a recognition greater than that of any other horizon on the sheet.

In addition to these outcrops, which have been especially defined, are the outcrops of the several other beds above and below the Mammoth. The outcrop of these beds have only been marked on the sheets where developed by ac-In all cases where the outcrops have tual mine working. been actually located, they are represented on the sheets by a full line in the conventional belonging to the bed which they represent. In places where only the probable location can be shown, the same conventional color with a broken line is used. On the edge of the sheet is printed a scale, on which the conventional color or line for each bed is shown; with the exception of names, tunnels and faults all the material, printed in black on the sheets, refers to surface features only. There has been constructed 18 cross sections which cross the sheets at right angles to the strike of the measures. The position of each of these sections is shown on the mine sheets by a full blue line, to which is added the number of the section.

While the same series of coal beds are worked on all the mine sheets and under somewhat similar conditions, there is sufficient difference in the character and thickness of the beds in different parts of the field, to warrant a description of each mine sheet separately. While this is necessary in general sense, in the study of individual coal beds and individual colliery openings, an intelligent understanding of

the connected structure of the basin is impossible without the consideration of all the sheets collectively.

While there is no point within the borders of the Western Middle coal field where the parting between the Mauch Chunk Red shale, No. XI and the Pottsville conglomerate, No. XII, rises to the surface to make a distinctly separate coal basin, yet there are many prominent basins and, anticlinals which modify the interior dips of the basins and materially effect the character and position of the mine workings. The completion of the sheets covering the entire length of the field, enable us to very accurately trace the more prominent axes along their entire length.

In the description of the location, extent and general structure of the basins and anticlinals of the field, it will be noted that the structure of the Mammoth bed is more prominently considered than that of any other. This occurs from the fact of a closer study having been made of its especial features in the contouring of the floor of that bed. A comparison of the Columnar sections which occur on each sheet with these contour curve lines will readily show the depth and position of the several beds above and below the Mammoth and will consequently give a clear idea of the general features of the basins in connection with these beds.

Mahanoy basin.

The most prominent of these flexures and the one from which the field is frequently named, and which has held so prominent a part in the coal production of this area is the Mahanoy basin.

East of the eastern edge of Mine sheet No. I the lowest coal measures of this basin are gradually lifted to the surface. The basin narrowing in its progress east causes the outcrop of the Buck Mountain and Lykens Valley coal beds and the top of the Mauch Chunk red shale to swing round the extreme end of the basin in their geological succession. In their progress east, all the coal measures above the Buck mountain bed have been lifted to day before reaching the eastern edge of Sheet No. I.

At the edge of Mine sheet No. I the outcrop of the Buck Mountain bed shows two district basins separated by a prominent anticlinal, the more southern of the two is the Mahanoy basin proper. 2300 feet east of the East Mahanoy tunnel of the Philadelphia and Reading Railroad is the extreme eastern outcrop of the Mammoth coal bed in the Mahanov basin. Its elevation here is 1450 feet above tide. From this point it rapidly falls until under the town of Mahanov City its probable elevation is 650 feet above tide. Further west, in the vicinity of the town of Ashland, the elevation of the bottom of the basin is about 1450 feet be-This is considered the lowest point at which the Mammoth coal bed is to be found in the Western Middle field, the difference in elevation from the surface being about 2300 feet, and from the southern outcrop over 2500 From this point there is a general rise of the basin towards the west.

The developments of the Mahanoy basin prove that its rise and fall along its axial line is not gradual, but on the contrary, more or less irregular. The extreme western outcrop of the Mahanoth bed in the Mahanoy basin is found north of the workings of the Ben Franklin colliery, about 6700 feet west of the eastern edge of Mine sheet No. VI. The elevation of the western outcrop, where it turns, in conforming to the dips of the basin, is 1500 feet above tide, very nearly the same as that of the extreme eastern outcrop.

The most marked feature of this basin is its steep regular north dips. The south dips are somewhat flatter than the north dips and are also very regular. The difference, however, between the two sides of the basin exists in the fact that while on the north side the dips are broken by a number of axes, entering the main basin from the northeast and northwest, the south side, with the exception of the break made by the expiring Locust Mountain anticlinal north of Gowen City on Sheet VI, is one unbroken monoclinal dip.

Much of the early mining in the Western Middle field was done in this basin, and to-day along the north dip, from a point 9600 feet west from the basin's extreme eastern end west for a distance of 15 miles, there is an almost un-

broken line of colliery workings, while on the south dip of the basin connected workings extend 4 miles further west. The bottom of this basin has recently been cut at the Lawrence colliery near Mahanoy Plane.

Such an event naturally suggests thoughts of the basins exhaustion. A little study of the contour lines in connection with the elevations of the outcrop and the bottom of the basin, together with the proportion of undeveloped area to that already mined, will show the future possibilities of this basin as a great producer from the Mammoth bed alone.

New Boston basin.

South of the Mahanoy basin and along the Broad mountain is the New Boston basin. This basin has been opened by the Middle Lehigh colliery. On sheets I and II the workings of this colliery are shown. Owing to the dimensions of the sheet, it is impossible to show the size and character of the entire basin. No contouring has been done to show the structure of the Mammoth coal bed, but a later publication will consider the New Boston and other Broad Mountain basins in their entirety and a future atlas will contain maps covering the area between the Mahanoy and Pottsville basins.

Separating the New Boston basin from the Mahanoy basin is a well defined anticlinal of the Pottsville conglomerate. The eastern outcrop of the Lykens Valley bed in the New Boston basin is shown about half a mile southeast of the southern mouth of the East Mahanoy railroad tunnel. Its extreme western outcrop is south of the southern edge of the sheets. The bed most worked in the New Boston basin is the Buck mountain. In addition to this bed the Seven Foot, Skidmore and both splits of the Mammoth are worked.

Middle Mahanoy basin.

Just north of the eastern extremity of the Mahanoy basin is that known as the Middle Mahanoy basin, the ananticlinal separating these two basins brings the Mammoth

to the surface at the Beaver Run colliery. Just west of this point at the Morris colliery the Buck Mountain bed is developed on both dips of the anticlinal. Near the outcrop of the Mammoth bed where it turns round this anticlinal, a local basin sets in which, though limited in extent, has a material effect in changing the shape of the contours.

The Mammoth bed at the extreme eastern end of the Middle Mahanoy basin, half a mile east of Beaver Run breaker, outcrops at an elevation of 1500 feet above tide; this basin falls rapidly west until at the Primrose colliery it is 900 feet above tide, the basin from here again rises until 1000 feet south of the Glendon colliery, an elevation of 950 feet above tide is reached, here it again falls reaching its lowest depth (650 feet above tide,) between Mahanoy City and Suffolk collieries, from here again rising it is lost in the Suffolk colliery workings on the north slope of the Ellangowan basin.

Ellangowan basin.

The dips of this basin are somewhat irregular, varying greatly in their amount. The basin, however, is marked as a specially productive and economical one to mine.

The Ellangowan basin proper which is now being very extensively developed in the mine workings of the Ellangowan colliery of the Philadelphia and Reading Coal and Iron Company, and from which a large and profitable production is anticipated, is of limited length. To the east, the more southern of the two synclinals into which it is divided, is lost in the mine workings of the Mahanoy City colliery, while its western end, at the line between Mahanoy and West Mahanoy townships, is lost in the inverted dips of the Bear Ridge overturn. The greatest approximate depth which the Mammoth bed in this basin reaches, is 300 feet above tide; its dips are generally flat and very favorable to successful mining.

The northern spur of the Ellangowan basin extends east of the Ellangowan breaker for a mile and three-quarters, finally disappearing in the workings of the West Lehigh colliery. The Ellangowan basin proper, together with its

northern spur, have not been as extensively worked as the several basins which surround them. Recent colliery openings, however, have been made, tending to the development of these basins, which will add much to the available tonnage of the Mahanoy region.

Shenandoah basin.

Still north of the Ellangowan basin is the Shenandoah basin, this basin is developed in the workings of the Mammoth bed, from the Packer No. 2 colliery, east to beyond the West Lehigh colliery, a distance of almost 7 miles. It includes within these limits the Lehigh Valley Coal Company's Packer collieries, as well as the Kohinoor, West Shenandoah, Kehley Run, Plank Ridge, Indian Ridge, Knickerbocker and West Lehigh collieries, all of which are noted in the trade for their extensive production and their record of profitable mining. The dips of this basin are more or less broken by local anticlinals and synclinals, the most important of which is the Shenandoah overturn. The Shenandoah and Bear ridge overturns are described in another portion of this report, (see page 987).

East of the West Lehigh breaker, 3000 feet or more, the Mammoth coal bed outcrops along the axial line of the Shenandoah basin. The basin continues to the east beyond the limits of the sheet. Its north and south dips are developed in the Meyersville and Pine Creek collieries in the Buck Mountain bed. The rise of the basin, however, is not sufficiently rapid to bring the outcrop of this bed to daylight within the limit of the sheet, at the point where it turns round the end of the basin. On 'this sheet the western end of the basin in the Mammoth bed is lost in the south dip workings of the Packer No. 2 colliery.

William Penn basin.

Beginning at the Turkey Run colliery, and running west is the William Penn basin. The extreme eastern outcrop of the Mammoth bed is shown at an elevation of 1200 feet above tide. The basin rapidly falls to the west until under

the town of Girardville it reaches its maximum depth, 600 feet below tide, from here it again rises regularly west, until 1000 feet east of the Bast Colliery slope it has reached an elevation of 300 feet above tide; from here it falls rapidly west, and is at once lost in the confused dips at the eastern end of the Germantown overturn.

Girardville basin.

South of the William Penn basin is another of lesser depth, first observed in the mine workings of Packer No. I colliery. It is called the Girardville basin, and falls rapidly west, and for a distance of 6000 feet from its intersection with the Packer colliery east gangway, where it is first observed, its course is almost parallel to that gangway. Under the town of Girardville, however, it swings to the south, and finally near the eastern line of the town of Ashland joins the main Mahanoy basin. The fall of this basin is continuous and very rapid; it is almost entirely undeveloped, so that a location of its depth and position is necessarily largely hypothetical. The shaft workings of the New Packer No. 5 colliery of the Lehigh Valley Coal Company will add much information of value in the development of this basin, and that of the William Penn basin to the north.

Centralia basin.

Separated from these basins by the broad, flat Locust Mountain anticlinal, is the Centralia basin, the outcrop of the bottom coal measures of which form such a prominent spur north of the outcrop of the main basins.

The Lykens Valley coal bed along this spur has been developed only by occasional shaftings. East of the village of Raven Run there are no workings in any of the coal beds, but west of this point the workings in this basin are continuous to one mile beyond the town of Centralia. The eastern limit of the Mammoth coal bed is about 2000 feet east of the junction of Butler, West Mahanoy and Union townships, Schuylkill county. The deepest point

of the basin is at the Continental colliery, where a depth of 800 feet above tide is reached.

West of this, however, the rise of the basin is very irregular. Its final western outcrop of the Mammoth bed, however, is reached 2 miles west of the town of Centralia, along the south branch of Shamokin creek. Future developments may prove the location of this outcrop to be incorrect. The location shown on the sheets was made from the best information extant, but was not sufficiently exact to establish a positive conclusion. At the Locust Run colliery, just north of the town of Ashland, the eastern end of the Germantown basin is developed in the Mammoth gangway, at the foot of the slope. It falls very slowly to the village of Germantown, where it reaches its greatest depth. From here it again rises to the east, until it is lost in the overturn dips at the Merriam colliery.

Coal Ridge or Montana basin.

North of the town of Centralia the workings of the Reno and Monroe collieries have developed the Coal ridge or Montana basin which extends northeast in a spur similar to that of the Centralia basin. East of Ravens Run the Lykens Valley bed has been opened along its outcrop and consequently lowest coal measures are well defined. The extreme eastern outcrop of the Mammoth bed is about half a mile east of the Reno colliery. The basin at its extreme eastern point is divided into two parts. The association of these two basins is so intimate that they have received the same name, the additional distinction being made by calling the southern one No. 1 and the northern No. 2. The southern or No. 1 basin falls very regularly and rapidly to a point just north of the Mt. Carmel colliery.

From this point for a short distance there is a slight rise in the bottom of the basin quickly followed by a gradual fall to a point south of the Pennsylvania colliery where the basin reaches its greatest depth in this vicinity, 400 feet above tide; from here it rises more or less irregularly until all traces of it are lost in the eastern workings of the Excel-

sior colliery. The northern Coal Ridge or Montana basin is that known as No. 2. Its course is parallel to that of No. 1 until the line between Columbia and Northumberland counties on Mine sheet No. V is reached. Here, by the flattening of the Pennsylvania anticlinal which separates these two basins, its course is materially changed, at one place in the vicinity of Green ridge running due east. West of this point it swings gradually to the south passing under the town of Shamokin, bearing south 72° 30' west. The elevation of the bottom of this basin is very irregular. Its fall from its eastern outcrop is west to the town of Mt. Carmel where it reaches an elevation of 100 feet above tide. from here it again rises to the Pennsylvania colliery, but developments at the foot of Pennsylvania slope No. 3 show that it falls towards the west. Near the western extremity of the Pennsylvania workings, it again rises to a point several hundred feet west of the eastern edge of Mine sheet No. VI. from here, however, the fall is regular and rapid across the width of Mine sheet No. VI to the western portion of Shamokin. Here it reaches an elevation of 800 feet below tide. From this point the dips are lost under the cover of surface wash, in the thickly wooded areas from this point west. The basin, in all probability, falls till it meets the Treverton basins when it gradually rises towards the extreme western outcrop of the Western Middle field. West of the Pennsylvania colliery the Coal Ridge or Montana basin is known as the Pennsylvania basin.

It will be noted that the Coal Ridge or Montana basin and the Mt. Carmel basin, the eastern ends of which are seen on these sheets are those which falling rapidly to the west attain, from their great depth and the number of coal beds which they contain, so great a commercial importance in the vicinity of Shamokin.

To the north of the Pennsylvania basin on Mine sheet No. V a portion of the Black Diamond basin is shown, the position of this basin has been determined largely by surface dips, it was debated for some time whether it was not a spur of the Pennsylvania basin instead of a separate one, the question depending on the existence of the anticinal, which

the mine sheets show as separating them. A careful consideration of the surface dips led the survey to the conclusion that the structure shown on the sheets is the accurate one.

South of the Pennsylvania basin (Montana No. 1), the workings of the Pennsylvania colliery have developed another basin, the Quaker Run, which is of considerable importance. Its course is almost parallel to that of the Pennsylvania basin; its fall is very regular and is continuous from its eastern origin west beyond the town of Shamokin.

Mt. Carmel basin.

The Centralia basin, already noticed as rising rapidly and bringing the basin in the Mammoth bed to the surface west of the Logan colliery, again falls to the west, producing what is known as the Mt. Carmel basin. The character of these two basins is very different, the dips of the Mt. Carmel basin being the flatter. Its most eastern development in the Mammoth bed is in the Mt. Carmel colliery of Thomas M. Righter & Co.

Its fall from here to the west is very rapid reaching its maximum depth of half a mile north of Mt. Carmel shaft colliery, from here it rises west and is finally lost in the north dipping measures of the Excelsior colliery. Its north dip is developed by the Mt. Carmel Shaft and Reliance collieries. Its south dips in the Mammoth bed do not rise to the surface and are as yet undeveloped.

Mt. Carmel Shaft basin.

The Mt. Carmel shaft basin, which is now being extensively mined by the Mt. Carmel shaft colliery, has its eastern developments in that colliery, while its western end is lost in the confused dips, developed by the Excelsior colliery.

Big Mountain basin.

At the Continental and Excelsior collieries still another basin is developed, the presence and location of which is also shown to the west, in the workings of the Big Mountain colliery. Its dips are sharp and well-defined. It is very narrow, falls rapidly west and is lost in the comparatively unexplored country between Shamokin and Trevorton.

Enterprise basin.

Still another basin is developed by the workings of the Enterprise colliery, which has its greatest depth at the western end of the Enterprise workings. Contrary to the other basins in the immediate neighborhood it rises to the west, the Mammoth outcrop at its extreme western end reaching daylight just south of the Burnside tunnel.

West of the town of Shamokin the coal measures are hidden by a deposit of wash on which there is a heavy growth of timber and underbrush. The exposures are very few and over very extended areas, there are no actual mining developments.

Between Shamokin and Trevorton there are several lines of shafting in which the outcrops only of the coal beds have been developed. Without mining development in this area it is impossible to accurately trace the direction and character of the anticlinal and synclinal folds. Near Trevorton the colliery workings have been opened quite extensively, but east of these for several miles the character of the flexures are undetermined. In the Treverton collieries two marked synclinal troughs are shown and are also proven in the outcrop of the lowest coal measures to the west. The outcrop of the Lykens Valley bed and the boundary of the limits of these measures is proven by continuous shaftings along the outcrop.

In addition to the basins which have been described there are many others in different parts of the field which are more purely of local interest; these latter have little effect in shaping the general character of the geology of the field, but their local importance in the development and profitable management of single collieries is very marked.

The probable exhaustion of the Western Middle field is a question of frequent discussion. Many of the basins,

both large and small, have been extensively worked and the coal exhausted over large areas. Aside from the consideration of the immense undeveloped areas in the Mahanoy and adjoining basins, which have already been extensively worked, there are many which are practically untouched, these in a large degree, emphasize the probability of a great future production.

Anticlinals.

East from the town of Frackville there extends the New Boston anticlinal which, bringing the Pottsville conglomerate to daylight, separates the New Boston from the main Mahanoy basin to the north. It is especially important as it brings all the coal bearing rocks to the surface, making a distinctly barren area between the two basins.

The anticlinal of greatest geological importance, in this field, is that of the Locust mountain. Near Raven Run, Schuylkill county, it first exposes the parting between No. XI and No. XII where the north and south dips meet on its crest; from here its elevation is quite irregular, although it at no point falls sufficiently to contain the outcrop of any coal bed geologically higher than the Buck mountain. Throughout its entire length it is a broad flat saddle, the dips of which show their marked regularity in the several gaps which are cut through it by the mountain streams. Its western limit in the coal measures is just north of Gowen City. Here it is the southern boundary of the coal measures of the Western Middle field, while at Raven Run it is on the opposite or northern sides. All the others on entering the field immediately fall and are rapidly covered by successively higher measures.

In addition to the Locust mountain anticlinal, and like it making well marked indentations in the boundary of the coal field, are the Mine Ridge, Red Ridge, Luke Fiddler and Trevorton anticlinals. These, together with the New Boston and Locust Mountain anticlinals, are the only ones which have a material effect in changing the direction of the coal fields boundaries. The other anticlinals, of which there are very many, while materially affecting the higher

coal measures expire east or west along their courses in the regular north and south dips of the basin. Most of these anticlinals have a material effect in directing the course and shaping the character of the advancing colliery gangways. In many cases near the centre of the basin they bring to the surface and expose extended outcrops of important coal beds. Several of these anticlinals have developed important overturns. In many places through the field the inverted dips of these overturns are entirely unworkable. The most marked of these are the Bear Ridge, Shenandoah, Germantown and Locust Spring. A description of each is given in the description of the mine sheet on which it occurs.

Mine Sheet No. 1.

At least five-sixths of the area embraced by this sheet is covered by coal measures, and the remaining portion by the Mauch Chunk red shale. With the exception of a very limited area in the vicinity of Delano (the drainage of which is east into Pine creek) the surface drainage of the coal measure areas embraced by this sheet is west through the branches of Mahanov creek into the Susquehanna.

At the time the sheet was completed there were but two railroad outlets for the coal production of the collieries within this area. One of these is the Mahanoy division of the Lehigh Valley Railroad; the other, the Philadelphia & Reading Railroad, which runs through the East Mahanoy tunnel. This tunnel, cutting as it does, through the lower coal beds down into the Mauch Chunk Red Shale was taken advantage of by the Survey in obtaining the facts necessary in the construction of a columnar section of the rocks which underlie this coal field.

Since the completion of the sheet the Pottsville and Mahanoy division of the Pennsylvania Railroad has not only been connected with that of the Lehigh Valley at New Boston, but branch lines have also been constructed into the towns of Shenandoah and Mahanoy city. The advantage of the presence of these three competing lines is readily perceived.

The outcrop of the top of the Mauch Chunk red shale was placed on the sheet from a survey made by the geological survey corps. The outcrop of the Lykens Vallev and the Buck mountain were located from the characteristics which are common to them and which we have already mentioned in their general description. The Skidmore and Seven Foot beds, which lie between the Mammoth and Buck mountain, are not defined by surface features or developed in colliery workings sufficiently to give an accurate location of their outcrop. They have been mined at the North Star, Webster, Hillside, Primrose, Coplay, Malvern, and other collieries on the sheets, so that if desired their outcrop may be approximately located by assuming their relative position to be the same on other portions of the sheet as at those which have been named. equally true of the Primrose and Holmes beds which overlie the Mammoth.

In the immediate vicinity and north of the town of Mahanoy City the coal beds have been extensively mined. These colliery developments have very minutely proven the structure and contour of the several basins as well as adding much to a knowledge of the size and character of the coal beds. East of these collieries, however, while a knowledge of the general structure of the basins can be obtained from surface indications little has been done which leads us to a detailed knowledge of the character and condition of the beds.

This sheet is especially interesting as containing the extreme eastern outcrops of the Mammoth coal bed in the Western Middle field as well as showing the development of the lower coal measures along the several anticlinal and synclinal folds, which, on this sheet falling to the west so materially, effect the geological structure of the basin.

It is also interesting as showing the geological connection between the main Mahanoy and the New Boston basins, the latter of which is at present so little developed. There are eight distinct coal beds mined on this sheet, of these the Holmes bed, with a thickness of 10 feet, is not extensively worked. The Primrose, however, which is the next coal bed above the Holmes is very extensively worked in both the main and middle Mahanoy basins. Its average thickness is about 10 feet. The Holmes bed, on this and Sheet No. II, is frequently confused with the Primrose bed. Each bed has been mined at adjoining collieries and their identification seems very plain. The confusion in the nomenclature of these beds has arisen more probably from trade reasons than from any misunderstanding as to their relative geological position.

The Mammoth bed has been extensively worked in each of the several basins on the sheet. A thickness of 7 feet for the top split, 8 for the middle split and 5 for the bottom split is therefore merely a record proven by mining developments. What the thickness and character of the same beds may be on the undeveloped portions of the sheet, it is, of course, impossible to state, but from the fact of their retaining their thickness over extended developed areas leads to a confidence that the same thickness and character will be maintained over the undeveloped areas adjoining. Below the Mammoth bed is the Skidmore, 6 feet thick; the Seven Foot, 6 feet thick; and the Buck Mountain, 11 feet thick. All of these beds are worked in each of the several basins on the sheet. Their thicknesses vary more than any of the beds which overlie them. The thicknesses given, however, are the best averages which can be suggested for this area.

Below the Buck Mountain is the Lykens Valley bed, the lowest coal bed in the series, its thickness as cut in the East Mahanoy railroad tunnel is but 3 feet. What the average thickness of this bed is over the entire sheet it is very difficult to determine, from the fact, that no colliery openings have been made upon it, neither have their been developments made along its outcrop by exploring shafts. The fact of the Lykens Valley bed having its minimum thickness at the eastern end of the field, while in the Trevorton collieries on Mine sheet VIII, at the western end of the field, it reaches its maximum thickness, coincides with a similar feature in the Southern coal field. In the eastern end of the Southern field it is very exceptional to find the Lykens Valley bed of workable thickness, in fact, it is un-

known in the colliery development of that portion of the region, but at the extreme western end of the Southern coal field it reaches its maximum thickness and condition. This thickening of the Lykens Valley bed near the western end of these two great basins is a point interesting in the study of the original deposition of this coal bed, not lessened by the commercial importance which the coal from this particular bed holds in competition with the other Anthracite coals known to the trade.

Mine Sheet No. II.

With the exception of a very small portion in its extreme southwestern corner Mine sheet No. II is covered with coal measures. This small portion outside of the coal measure is in the Mauch Chunk Red Shale. The Lykens Valley coal bed has been outlined on this sheet from surveys locating an exposure of its outcrop at several points. It is at no point opened by colliery workings. The Buck Mountain bed is worked to some extent and its outcrop determined largely from these workings.

The outcrop of the Mammoth bed is shown by actual mining developments at every point on the sheet where it The Big Tracy, 4 feet thick, the reaches the surface. Diamond, 7 feet thick, Little Orchard, 3 feet thick, and the Orchard, 11 feet thick, are found in the Ellangowan basin. All but the Little Orchard bed have been worked by water level drifts and from the developments in these drifts the above thicknesses were obtained. these beds and the Mammoth are the Primrose and Holmes. the former 8 feet thick and the latter 13 feet thick. The same confusion of nomenclature between the Primrose and Holmes which has already been mentioned in the description of Mine sheet No. I occurs on this sheet. The thickness of the Mammoth bed on this sheet is greater than that on sheet No. I the top split averaging 12 feet, the middle 8 feet, and the bottom 15 feet. The thickness of the slate also between the top and middle splits is here reduced from 80 to 40 feet. The Mammoth bed

has been very extensively worked on this sheet, both in the Mahanoy basin, between Gilberton and Mahanoy City, and in the Shenandoah basin in the vicinity of the town of Shenan-There still remains, however, an extended area of Mammoth coal in the Mahanoy basin as well as in the Ellangowan basin and its northern spur. Some of the heaviest coal producing collieries in the region are to be found on this sheet. They are mainly located in the vicinity of Shenandoah, and almost the entire production of these collieries is mined from the Mammoth bed. In addition to the Mammoth bed the Skidmore 4 feet thick, The Seven Foot 7 feet thick, and the Buck Mountain 12 feet thick have also been worked over limited areas. The most marked difference in the workings shown on Mine sheets Nos. I and II is that on mine sheet No. I, the Mammoth and the beds beneath it are the ones most extensively worked; while on sheet No. II which adjoins No. I on the west, the Mammoth and the beds above are extensively worked and the workings in those below the Mammoth comparatively limited.

There is probably no area in the Anthracite region which contains so much that is interesting in structural geology as that embraced by mine sheet No. II. The coal has been mined and the colliery workings advanced to such an extent that even the local secondary rolls of the several basins have been generally developed.

The most marked feature in the geology of the sheet is the presence of the Shenandoah and Bear Ridge overturns. The former is first observed in the workings of the Knickerbocker and Ellangowan collieries. In these workings as well as those of the Yatesville colliery there are developed a number of local rolls of greater or less extent which form secondary folds in the Shenandoah basin. Extending towards the west these folds become sharper, their dips steepen and they are brought very closely together. At the western end of the highest lift gangway in the Mammoth bed, of the Ellangowan colliery, it encounters a very sharp anticlinal and swings round on to its north dip. From this point west for a distance of four miles the north dip of the Shenandoah basin is overturned.

At the Ellangowan colliery at a point which we have already mentioned, the overturn dips are perpendicular or nearly so, but continuing to the west the overturn is more marked, at many places being paralled to the regular south dip of the Shenandoah basin.

Along its entire course the horizons containing both dips of the Mammoth bed are exposed on the crest of the over-At many points, more especially at its turned anticlinal. eastern end, it is impossible to find the outcrop of the Mammoth bed along the overturned dip, in fact, between the Ellangowan and Knickerbocker collieries there has been little coal discovered between the outcrop of the Buck Mountain on the south dip of the Ellangowan basin, and that of the Holmes bed on the perpendicular north dip of the Shenandoah basin. Towards the western end of this overturned anticlinal, the dips of the overturn, while showing a greater overlap, do not show the same pinching of the measures, and in the vicinity of Packer colliery No. 3, the outcrop of the Mammoth on the overturned dip is exposed at several points.

This overturn crosses the western edge of Mine sheet No. II, and is entirely lost in the south dip workings of the Packer No. II colliery, located on Mine sheet No. III.

The dips of the Bear Ridge overturned anticlinal are equally well developed, its eastern portion being contained on this sheet. Its basin is a continuation of the Ellangowan basin to the west one of the marked characteristics of which is its extended flat dips. Unlike the Shenandoah anticlinal, approaching it from the east, the dips of the Ellangowan basin are unbroken by local folds, and retain their low dips to within a few hundred feet of the point where the overturn is developed.

This overturn is first seen just north of the old Furnace colliery, and from that point extends west along the south side of Bear Ridge. Like the Shenandoah overturn, the measures along the crest of the Bear Ridge overturn anticlinal have been eroded to below the Mammoth bed, thus exposing this horizon on both dips. This overturn differs from the Shenandoah overturn in the fact that its dips are

the same for almost its entire length. It has the additional peculiar feature, rarely seen in the Anthracite coal measures, of exhibiting a parallelism between the north and south dips of one basin, and the south dip of an adjoining basin.

This is illustrated by the parallelism of the dips in both the Bear Ridge overturned basin, and in the south dip of the Mahanoy basin. An interpretation of the geological structure of this ridge, from surface features alone, would be impossible. The colliery workings, however, have made developments which have given us quite an accurate knowledge of the position of the coal measures in this disturbed area. Unlike the overturned dips of the Shenandoah anticlinal, those of this overturn are at no point workable.

This overturned dip continues west beyond the western limit of sheet II, where it is last seen at the town of Girardville.

Mine Sheet No. III.

On Mine sheet III, there are three areas about two thousand feet wide, which contain no coal. Two of these cross the entire width of the sheet, while the third along the Locust Mountain anticlinal crosses the sheet line from the east, and is barren of coal until it reaches the Raven Run colliery. This latter area is about eight thousand feet long and two thousand feet wide, and together with the other two strips of barren area is covered by Mauch Chunk red shale. The balance of the sheet is within the coal measures.

The outcrop of the Lykens Valley bed has been located on the sheet from general surface indications, and its associated topography. At no point on the sheet is this bed opened either by colliery workings or by trial shafts along its outcrops.

The Buck Mountain bed is worked at a number of points, but nowhere so extensively as in the vicinity of Raven Run; it has been worked at so many points, however, that its outcrop is thereby very accurately determined.

The outcrop of the Mammoth bed is developed on all parts of the sheet by the colliery workings. The beds which

overlie the Mammoth are not extensively worked, in fact, with the exception of the Preston, Girard and William Penn collieries, the upper series of beds is untouched, although in one or two places where they have been cut in rock tunnels driven to develop other beds. Within the limits of the sheet there are no colliery workings on either the Big Tracy bed, which is 7 feet thick, the Diamond bed which is 4 feet thick, or on the Little Orchard bed which is 6 feet thick. These beds have only been proven in shaftings on different portions of the sheet and in rock tunnels, no workings have been opened upon them. The Orchard bed is opened at the Preston No. I colliery, where they have also worked the Holmes.

The Orchard bed here shows a thickness of 5 feet and the Holmes bed 10 feet. The Primrose is shown to be but This thickness for the Primrose is abnor-3 feet thick. mal, and the positive identitification of both the Holmes and the Primrose may be questioned. On this sheet all the benches of the Mammoth are together making a bed the thickness of which will average 25 feet. The Mammoth on this sheet, as on all others, is very extensively mined, although from the nature of the dips of most of the basins the workings have not extended over so great a horizontal area as those on sheet No. II. still remains an immense amount of Mammoth coal in the William Penn and Girardville basins and their secondary rolls, which is yet to be mined. The No. 5 shaft of the Lehigh Valley Coal Company at Girardville, which has been sunk since the completion of our sheets, will develop both of these important basins.

There is no mining on this sheet on the Skidmore and Seven Foot beds, from the fact that they have not usually been found of workable thickness. This condition is greatly in contrast to that of the same beds on sheet No. I, where each of them are extensively worked. The Buck Mountain, however, is found with an increased thickness; it is mined very little on the southern portion of the sheet, but on its northern portion, in the vicinity of Raven Run, and on the south dip north of the Connor, Hammond and Pres-

ton collieries, mine workings in this bed extend over very large areas. The thickness of the Buck Mountain over these areas averages 15 feet. The workings of the Girard Mammoth colliery not only developed the Buck Mountain bed along the center and on the sides of the Centralia basin, but has also extended its workings to the crest of the Locust Mountain anticlinal, where these workings are narrowly separated by the axis of the anticlinal from those of the Hammond colliery on the opposite dip.

It will be observed that the coal production of this sheet has come almost entirely from the Mammoth and Buck Mountain beds, the other beds being either entirely unworkable or mined over very limited areas.

The Bear Ridge overturn which has before been noted on Mine sheet No. II, continues west on Sheet III as far as the town of Girardville. It carries the same characteristics with it on this sheet as those which it held on Sheet II, both as to the condition of the coal beds found in the overturn, and in the parallelism of the several dips which we have already noted.

In the southwest corner of this sheet is located the Mahanoy plane, of the Philadelphia and Reading railroad which for many years has hoisted the coal from the Mahanoy valley to the top of the Broad mountain, from which point the grade steadily descends towards tide water. The difference of elevation between the top and bottom of the plane is 353 feet, the elevation of the top of the plane being 1484 feet A. T. It will also be noted that while all of sheets I and II, and a large portion of sheet III, are in Schuylkill county, the northwestern corner of sheet III is in Columbia county.

Mine Sheet No. IV.

The southern portion of this sheet is included within the borders of Schuylkill; its northern portion is in Columbia county while along its western edge there is a portion of limited extent which is included in Northumberland county.

This sheet is covered by coal measures with the exception of a very limited area along the crest of Mine Ridge in the northeast corner of the sheet and also an additional barren area along the Mahanoy mountain, near its southern edge. This latter area runs across the entire length of the sheet and is about 2000' wide. Both these areas are in the Mauch Chunk red shale.

The workings of the Gordon colliery on the Lykens Valley bed, which extend over the borders of the sheet from the west, together with workings on the same bed of limited extent in the vicinity of Centralia and Montana, give the location of its outcrop very accurately in this particular neighborhood. Along its most southern outcrop it is easily located by its accompanying topography but along the south dip of the Mine Ridge anticlinal, just north of Centralia, anything more than an approximate location of its position is impracticable.

The Buck Mountain bed is worked at a number of points on the sheet. These colliery developments very accurately locate its outcrop. It is most extensively worked on the east and west sides of Mine run along the Locust mountain anticlinal, but west from this point as the anticlinal broadens there are neither workings nor shaftings along the outcrop by which to determine its position.

The Mammoth bed as on the other sheets to the east has its outcrop developed over almost the entire area of the sheet by the extended colliery workings which have developed its coal. There is an exception to this however, at the extreme western end of the Centralia basin where the deposit of wash along the south branch of Shamokin creek is so great that it is impossible to determine the outcrop of this bed.

A study of the geology of this sheet is interesting from the fact that in the vicinity of Ashland the Mahanoy basin is found of greater depth than at any other point in the Western Middle coal field. The great depth of the basin here is a very important point in the consideration of the exhaustion of the coal from this field. It is also here that the anticlinal, which to the east separates the Girardville from the Mahanoy basin disappears and to the west these two basins combine in one regular synclinal trough.

The Locust Mountain anticlinal, the dips of which are so prominent in the Buck Mountain bed on the eastern end of this sheet as well as on Mine sheet No. III. gradually broadens and flattens in its progress west. This is true to such an extent that, instead of containing extended areas of Buck Mountain coal with flat dips and general surroundings tending towards profitable mining, it contains quite an extended area underlaid by no coal above the Lykens Valley, which probably at no point rises to the surface. This bed has never been opened along the Locust Mountain anticlinal, and nothing therefore is known of its thickness or condition. The beds above the Mammoth are worked over limited areas.

In the Mahanov basin, the Big Orchard 4', the Primrose 8' and the Holmes 5', thick, have each been worked over limited areas. That these thicknesses will increase or decrease on other portions of the sheet it is impossible to determine. Except in the Coal Ridge basin the Mammoth bed occurs only as one bed and not separated into several splits as is frequently seen on the other sheets. Its thickness will probably average 25'. A bed said to be the Skidmore is opened on an overturn on Little Mine run. This is the only point on the sheet where this bed has been developed excepting in a rock tunnel at Logan colliery from which no gangways are driven. The Seven Foot bed is not generally recognized on the sheet though it may be represented by one of the several small leaders which occur between the Skidmore and Buck Mountain beds.

The Buck Mountain bed is worked at a number of points but most extensively along the Locust Mountain anticlinal south of the town of Centralia. West of Locust run on its south dip and west of Centralia on its north dip the workable thickness of the bed becomes questionable and from these points west we have little practical knowledge of the value of the bed. On the other portion of the sheet its probable average thickness is about 10'.

One of the prominent geological features of the sheet is

the Germantown Overturn anticlinal. This anticlinal is developed on Mine Sheet III as far east as the extreme eastern end of the Packer No. I colliery, from here it runs west under the town of Girardville separating the Girardville and William Penn basins. It reaches its lowest point at the eastern end of Girardville on Mine sheet II and rises with more or less regularity to the Bast colliery. Its dips continue very regular until within about 1,000' of the Bast colliery underground tunnel where the several dips of the anticlinal steepen and before the tunnel is reached these dips become overturned. The top of the anticlinal is here also eroded so that the overturned dip in the Mammoth bed is exposed along its outcrop. From the Bast colliery tunnel west the overlap increases very rapidly.

At the Locust Run colliery the outcrop of the Mammoth bed on the overturned dip swings rapidly south and at Cleaver and Yocums colliery joins the regular south dip of the Mahanoy basin. The overturned dips continue towards the west, the top of the anticlinal in the Mammoth bed however being below the surface. The outcrop of the overturned dip in this bed, again shows at the old abandoned Cambrian colliery and continues west overlapped along its course until in this condition it crosses the western edge of Mine sheet No. V.

The Germantown overturned anticlinal is remarkable as producing a parallelism of dips like those of Bear ridge, between the south dips of the Germantown overturned basin, the north dips of the same basin (which are the overturned dips) and the south dips of the Mahanoy basin, making three of the dips of two separate basins parallel.

Mine Sheet No. V.

This sheet is known as the Mt. Carmel sheet. It extends from a point one-sixth of a mile east of the town of Mt. Carmel, Northumberland county, which is far enough east to include in its north-eastern corner the line between Northumberland and Columbia counties. Its western limit is about 17000 feet west of the town of Mt. Carmel. With the excep-

tion of a very small portion in its south-western corner the sheet is covered by coal measures areas. This small portion being underlaid by the Mauch Chunk red shale in the valley next south of Locust mountain. Mine sheet V embraces collieries which work the following coal beds: The Upper Member of the Lykens Valley or No. I, the Buck Mountain or No. V; The Seven Foot or No. VI; Skidmore or No. VII; the Lower Member of the Mammoth bed or No. VIII; the Upper Member of the Mammoth bed or No. IX; and the Holmes or No. X. The relative thickness and position of these beds together with that of the rocks between them is shown on the columnar section printed on the border of the sheet. The lower portion of the section, which includes several leaders of coal, too small for mining, was developed in the water level tunnel driven at the Gordon collieries in order to cut the Lykens Valley bed No. I, from which all the coal the colliery pro-The middle portion of the section, duced was taken. including all the coal measures from the bottom of the Lykens Valley No. I to the bottom of the lower member of the Mammoth No. VIII, was taken from a cross section made by the engineers of the Philadelphia Coal and Iron Co. through the Helfenstein slope. The data for this section was obtained from the mine workings of the several collieries in the Mahanov basin, as well as from trial shafts, which had been sunk on the outcrops of the unworked beds.

The upper portion of the section, which includes the coal measures from the Lower member of the Mammoth bed to the Primrose bed, was constructed from sections measured by the Geological Survey in the underground tunnels of the Pennsylvania colliery, and also from a trial shaft which exposed the outcrop of the Primrose bed No. XI. These beds are all of greater or less importance on different parts of the sheet. Those which on some parts of the sheet are most profitable to mine are at other points unworkable. This is due to the thickening and thining of the beds, and seems to be especially the case of the beds beneath the Mammoth.

The section, therefore, while giving the best possible il-

lustration of the general structure of the coal measures embraced by this sheet can hardly be exhibited as a representative section of the entire area. The coal beds above and including the Mammoth show about the same thickness on all parts of the sheet. But this is not true of the beds below. In the Mahanoy basin the beds below the Mammoth have been developed by mine workings but in the basins to the north, notably the Mt. Carmel, Pennsylvania, and Black Diamonds basins such is not the case. In the Pennsylvania colliery on the north dip of the Pennsylvania basin, a turnel has been driven which cuts the Seven Foot bed No. VI and the Skidmore bed No. VII. The section of coal bed No. VII measured in this tunnel shows:

Top, hard sandstone	e.																				
Coal,																				0′	4"
Bone,																				0'	2''
Good coal,																				0	5′.
Shelly coal,																				0′	6'
Bottom, hard slat	e.																				
(Poto)																				1.	- F 11
Total,	•	٠	٠	٠	•	•	٠	٠	•	٠	٠	٠	٠	٠	٠	٠	٠	٠	٠	T.	Ú.

It was at the time impossible to obtain a section of bed No. VI as the entire exposure of the bed, which was cut on the axis of an anticlinal a few feet below the level of the tunnel, was entirely under water. There is no other point in the Pennsylvania, Black Diamond or Mt. Carmel basins on Mine sheet V, where the beds underlying the Mammoth have been developed in the mine workings. Bore holes in the vicinity of Mt. Carmel, however, show the thickness of these beds to be very much reduced.

These beds have been worked over so limited an area that it would be clearly unfair to present them as representative sections. There are, however, with the exception of the bore holes in the vicinity of Mt. Carmel, no other developments which would indicate their character and thickness.

The development of the Lykens Valley bed to so great an extent as that of the Helfenstein colliery is exceptional within the limits of the Western Middle coal field. The North Franklin collieries on Sheet VIII, the Ben Franklin colliery on the adjoining mine Sheet No. VI and the Gordon colliery also on Sheet V being the only other extensive colliery openings on this bed, outside the limits of the Lykens Valley district of Schuylkill and Dauphin counties.

Inquiry is often made as to the probable condition of the Lykens Valley bed in the undeveloped portions of the Western Middle field. This question is probably suggested by the developments on this bed on Sheet V which have no parallel on the four sheets of the series to the east. In the present state of mining development an opinion on the value of this bed, except where positively shown is largely a matter of conjecture.

On Sheet V the extent of the workings of the Helfenstein and Gordon collieries, together with the sections of the beds which were there developed, and the section cut in the Diamond drill bore holes at the Mt. Carmel colliery are the only data which at present give any information on this point. An average section of the Lykens Valley bed at the Helfenstein colliery is:

```
      Rock top.
      Soft and shelly coal,
      1' 0''

      Slate,
      5''

      Coal good,
      8' 5''

      Rock bottom.
      and at the Gordon colliery is:

      Rough coal,
      2' 11''

      Slate,
      1' 0''

      Coal,
      5' 10''
```

The same bed was cut in the Diamond drill bore hole at the Mt. Carmel colliery, the record of which was given to the Survey by Mr. Thomas Righter, the indications are, however, that this hole was put down in confused dips and did not develop the bed at its normal thickness.

The upper member of the Lykens Valley bed No II has been developed at several points on Mine sheet No. V in trial shafts sunk on its outcrop. Its average thickness is two feet, so small that unless found in better development at some other point it need not be considered among the workable beds of the sheet for many years to come.

The position and thickness of the Buck Mountain bed on this sheet has only been determined by trial shafts along its outcrop. Recent developments have been made by series of trial shafts along the Red Ridge anticlinal in the northwest corner of Sheet IV. These explorations while they do not extend as far west as Sheet V indicate that both dips of the Buck Mountain bed outcrop on this sheet. Along this anticlinal an attempt was made to locate the crop, but without the aid of trial shafts it was considered impracticable. The thickness of the Buck Mountain bed in the shaftings referred to on the western border of Sheet IV is 6 feet.

The Skidmore bed is developed and quite extensively worked in the Merriam, Monitor and Locust Spring collieries of the Philadelphia and Reading Coal and Iron Company in the Mahanoy basin. The fact that they are profitably mined is indicated by the extent of the workings.

The identity of this lower bed is somewhat confused with that of the Mammoth. The Mammoth bed, the lower split of which is No. VIII and the upper split No. IX, exhibits on this sheet to a very great degree a marked characteristic which is seen in many parts of the Anthracite Coal Fields, viz: The separation of the several benches into separate and distinct coal beds with intermediate thicknesses of sandstone and slate. At many points, notably the collieries located along the south dip of the Mahanoy basin and in portions of the Mt. Carmel shaft colliery the Mammoth occurs as one bed.

In other portions the Mt. Carmel shaft colliery the lower member of the Mammoth bed is much more extensively mined than the upper, while across the Mt. Carmel basin at the Pennsylvania colliery, only a few thousand feet north, the upper member is extensively worked over large areas and the bottom member but slightly worked. This fact is worthy of note, in connection with the already mentioned changes peculiar to the Mammoth bed in this and other vicinities.

In the same collieries it is divided into two and sometimes three distinct members. This makes the identity of beds in different areas very difficult, as in many cases two or more beds having a workable thickness and whose individuality is well established at other points are joined and make but one workable coal bed. This feature is especially marked in the Mahanov basin, in fact even with the extended workings at the Merriam, Monitor, Locust Gap and Locust Spring collieries the identity of all the beds is at present uncertain. An especial study of the beds at these collieries will shortly be made by the Survey with the object of exhibiting the accurate identity of the beds worked. It is believed that this can be very satisfactorily done when the mine workings have been further ad-The present uncertainty in the identity of the individual beds is well illustrated by an incident which occurred in connection with the Monitor and Locust Spring The main slopes of both collieries are sunk on the supposed bottom bench of the Mammoth. In the Locust Spring colliery a tunnel was driven north 120 feet cutting the Skidmore bed (so called) at that distance. An air way in the east gangway opened from this tunnel was driven up the pitch and "holed" into the west bottom gangway from the Monitor colliery slope. This gangway is on what has always been accepted as the bottom member of the Mammoth bed, the slate separating this bed and the Skidmore bed elsewhere having disappeared and the two beds at this one point forming but one. This fact alone throws great doubt on the present identity of the beds, a doubt which can only be removed by the advance of the mine workings and a connected study of adjoining collieries.

The Holmes or No. X bed is worked at but one point on the sheet, in the Pennsylvania colliery, where it is developed by the underground tunnel driven north from the upper member of the Mammoth bed. The following section was taken at the face of this tunnel:

Top, hard sandstone.					
Slate,		 	 	. 1'	10'
Rough coal,		 	 	. 1'	8′′
Coal,		 	 	. 1'	2'

, a					

The Locust Mountain anticlinal, which plays such a prominent part in the geology of the field on the sheets to the east, also crosses the entire width of Sheet No. V. dips of the anticlinal are plainly seen in the gap cut through Locust Mountain by the waters of Locust creek in their course to the north. Unlike the sheets to the east there are almost no explorations made along Locust Mountain in the beds which underlie the Mammoth, the probabilities are, however, that the Skidmore and Seven Foot beds outcrop on both dips of the anticlinal along the entire length of the sheet and that the outcrop of the Buck Mountain bed is exposed from the eastern edge of the sheet to a point several hundred feet west of the gap made by Locust creek. The thickness of the long interval between the Buck Mountain and Lykens Valley beds precludes the possibility of this bed rising to the surface on the crest of the anticlinal.

The fact that the beds which underlie the Mammoth have not been explored along this anticlinal makes it impossible to give any definite estimate of their character or thickness. Such an estimate would be purely conjecture.

One feature worthy of mention is that the steepest dips which have been developed along the entire Mahanoy basin are found on this sheet; at several points they very nearly approach 90 degrees.

The Germantown Overturn basin, which has been referred to on Mine sheet No. IV, crosses the eastern edge of Sheet No. V, where it is encountered in the workings of the Merriam, Monitor and Locust Gap collieries. Its character is similar to that on Mine sheet No. IV, the overlap being equally extended. The structure and position of the coal beds in the Merriam and Monitor collieries is made still more complicated by the development of a second overturned anticlinal. The mine workings of these collieries have so far developed these abnormal dips that the construction of a very accurate section illustrating their various flexures is possible at a number of points.

On the western side of the sheet a third important overturned anticlinal has been developed in the workings of the Locust Spring colliery. A hoisting shaft was recently sunk

to a counter gangway at this colliery and from its foot an airway driven to the surface. This airway struck the summit of the overturned anticinal, thus accurately defining its location. 300 feet west of the mouth of this hole, trial shafts have been sunk, which develop the outcrop of the Mammoth bed on both dips of the anticlinal. The south outcrop of this anticlinal will be still further developed as the workings from the New Locust Spring hoisting shaft, are advanced to the west. The bottom of the overturned basin attending this anticinal on the north has not yet been reached by the workings of the Locust Gap colliery. Succeeding lifts from this colliery will, however, undoubtedly come in contact with it.

It will be noted that the Philadelphia and Reading, the Northern Central and the Lehigh Valley railroads are all represented in this portion of the field.

The drainage of the areas on the sheets to the east has been generally into Mahanoy creek, but on Sheet V, near its southwestern corner a watershed occurs, which throws the drainage into Shamokin creek, and makes the grade of the railroads favorable to a western trade.

Mine Sheet No. VI.

The Western Middle field is generally divided by the coal trade into the Mahanoy and Shamokin districts. Sheet No. VI, which is entirely within the boundaries of Northumberland county, contains a very small portion of the extreme western endof the Mahanoy basin and includes within its boundaries the most important part of what is usually known as the Shamokin district.

The town of Shamokin, from which the sheet gets its name, is located in its extreme northwestern corner. The drainage of the area embraced by the sheet is through Shamokin creek and its tributaries.

With the exception of a small portion in the southwest corner, the area of the sheet is included within the coal measures. In the vicinity of Shamokin the basin is very steep, and with the possible exception of a small area near Ashland, contains a greater number of workable coal beds than at any places in the Western Middle field.

The parting between the Mauch Chunk red shale and the Pottsville conglomerate has been very accurately located by survey. It follows in an almost parallel direction, the wagon road through Helfenstein and Shamokin, until it reaches the top of Locust Mountain, where it swings to the northeast and turns west along the rise of the Locust Mountain anticlinal; from here it follows the regular north dip to the west.

The Lykens Valley coal bed has been extensively worked at the Ben Franklin colliery by Douty and Baumgartner, with this exception the Lykens Valley bed on this sheet is undeveloped. West of the Ben Franklin colliery no developments of any kind have been made on this bed. While these workings at the Ben Franklin colliery are the only ones on the sheet, others have been made at the Cameron colliery just north of the sheet in the Lykens Valley bed which will suggest some idea of its thickness along the northern portion of the sheet.

There is a possibility, hardly a probability that the coal bed of the Mt. Franklin colliery is identical with the Lykens Valley bed. It is however more likely a leader between that bed and the Buck Mountain.

The Buck Mountain or No. V bed has been opened at the Brady and Greenback as well as at the Enterprise collieries. The actual mining of the Buck Mountain coal bed on this sheet has been quite limited there being no exposures along its outcrop other than those developed by the progress of the mine workings.

The Skidmore bed has been worked only at the Enterprise colliery, a section is as follows:

Rock top.														
Coal,													4'	3"
Slate, .														2"
Coal,														
Rock botto														

The Mammoth bed is extensively worked on the sheets, although there is still a large area east of Shamokin along Quaker run in which all the beds are untouched. On

this sheet the Mammoth is almost invariably worked in two splits, one being worked to the same extent as the other.

The beds above the Mammoth are extensively worked just south of the town of Shamokin at the Henry Clay, Peerless, Frank Gowan, Franklin, Clinton, Alpha and Daniel Webster collieries, the thicknesses of these beds are as follows: Bed No. XVI, 5', Bed No. XV, 6', Bed No. XIV, 8', Bed No. XIII, 6', Orchard Bed No. XII, 4', Primrose Bed No. XI, 7' and Holmes Bed No. X, 3'.

The most notable features on this sheet are the outcropings along their axes of the Mahanoy basin and of the Locust Mountain anticlinal. This basin and anticlinal are prominent on all the sheets to the east and their disappearance from the coal measures, and the succession of another series of basins and anticlinals succeeding them is a matter of great interest.

It will be noted that in the exploration of the Mahanov basin the flexures developed on Mine sheets I and II and all of those on Mine sheet III, with the exception of the Centralia basin, are lost and that all the flexures which appear west of the extreme end of the Locust Mountain anticlinal are, with the same exception, those which have first made their appearance on sheets IV and V. In the description of Mine sheet No. V reference was made to the overturned anticlinal developed by the Locust Spring colliery, and mention made of the exposures of the outcrop of the Mammoth bed on both dips of the overturn. After crossing the western edge of Mine sheet VI the anticlinal broadens, thus increasing the distance which separates the main Mahanoy basin from its more northern spur which is first developed between the Locust Gap and the Locust Spring collieries. The Locust Spring overturn dip is in the northern of these two basins. crosses the eastern edge of Mine sheet VI, the overlap extends some distance across the basin but before it reaches the extreme western end of this northern spur the overturn changes to a perpendicular dip. There are no shaftings along the outcrop of the northern basin, so that its position is necessarily approximately located from surface exposures without the aid of trial shafts. The Mammoth bed in the more southern or main Mahanoy basin extends west of the edge of the sheet a distance of 6700 feet. Its outcrop is located by a series of trial shafts. The elevation of both outcrops of the basins at their extreme western end is about 1500 feet above tide which is within 100 feet of the elevation of the extreme eastern exposure of the Mammoth bed in the Mahanoy basin on sheet I. The beds underlying and overlying the Mammoth in the two spurs which cross the west line of Sheet No. VI have not been opened either by shaftings or mining. There thickness and condition is therefore impossible to determine. The fact of the existence of the overturned anticlinal which separates them adds much more doubt to their condition.

A prominent feature on Sheet VI is the Big Mountain anticlinal. The workings of the Excelsior collieries have developed the outcrop of the Mammoth bed on the north, east and south dips of this anticlinal while the Big Mountain colliery has developed the north, south and west dips of the anticlinal. Along its course Shamokin creek cuts through it almost at right angles to the axis and here exposes the outcrop of the Buck Mountain bed. The erosion along this outcrop is very irregular. In the vicinity of the Greenback gap there is over 2000 feet between the outcrops of the north and south dips of the Mammoth while just south of the Buck Ridge colliery there is but 300 feet between the same exposed dips.

Mine Sheet No. VII.

The southern portion of this sheet, probably one-third of its area, is outside of the coal measures. A large portion of the balance is entirely unworked. No railroads have been constructed extending west of the Bear Valley shaft. The entire drainage is west into Shamokin creek, which crosses the border of the sheet near its north-eastern corner. The outcrop of the Lykens Valley bed is located throughout its entire length by actual survey. The only openings along the south side of the basin were found on

the Wilson and Dewart tract. One of these was a slope which was sunk about 25 yards, and from which short gangways have been driven east and west. The thickness of the bed is about 10 feet. Other portions of this outcrop were located from the characteristic topography which usually accompanies the Lykens Valley bed. It is worthy of note that on all the existing maps there is a marked break in the continuity of the Lykens Valley crop, south of the Bear Valley shaft workings. The form of this change of direction would indicate a saddle and basin, such do not exist in the Lykens Valley bed, and the direction of the outcrop is regular and continuous. This formation was probably suggested by the outcrop of the Mammoth bed rising from the Enterprise basin, and the Lykens Valley outcrop was placed on the maps parallel to that of the Mam-The slightest observation on the ground, however, dispels this idea.

The Buck Mountain bed is cut in the Burnside tunnel. A section shows:

Top.													
Coal, good,												2	0
Slate,													2'
Coal, good, .								•	•				9'
Slate,													2'
Coal,												3′	0,
Rottom													

This is the only point on this sheet where the Buck Mountain bed has been mined. Whether it will maintain or increase this thickness is purely a matter of conjecture. The Seven Foot and Skidmore beds Nos. VI and VII are not mined on the sheet so that it is impossible to make any estimate of their value.

The Mammoth bed on this sheet, as on Mine Sheet VI, occurs in two splits, both of which are worked. Wherever the bed has been opened the average thickness of the lower member No. VIII shows 9', while the upper member No. IX shows 7'. On portions of the sheet a third member occurs 6 feet thick.

About one-half of the area of the coal measures on this sheet are entirely undeveloped by mine workings, and with

the exception of a single line of trial shaftings in about the center of this undeveloped area, there is almost no exposure of the outcrop of any of the coal beds in the series. This area is covered with wash, and is so heavily overgrown with underbrush and timber, that it is impossible to trace the synclinal and anticlinal axes, and without further developments, it is impossible to express in detail an opinion of any value on the character and condition of the coal measures which are here contained. There is no reason to suppose that the coal within this area is not equal in thickness and purity of that in the vicinity of Shamokin.

Mine Sheet No. VIII.

All of the area covered by this sheet, is in Northumberland county, and is the last and most western of the series in the Western Middle coal field. Of the three divisions, Mahanoy, Shamokin and Trevorton, in which the Western Middle coal field is generally divided, Sheet No. VIII may be said to include all of the Trevorton district.

The watershed which separates the drainage areas of Carbon run and Zerbe runs, is at the eastern edge of Sheet VIII. This watershed defines the boundary between the Trevorton and Shamokin districts. The outlet of Zerbe run is through the gap in the mountain at the North Franklin No. I colliery. Within the area drained by this creek are the workings of the Trevorton collieries. Less than half of this sheet is covered by the coal measures, the basin rapidly narrowing as it approaches its western end.

The outcrop of the Lykens Valley bed is well proven by a series of shaftings, all of which have been located by survey. On the maps of the operating companies, the extreme western end of the basin is located 2½ miles west of the Trevorton gap, and is shown as a single curved line. The actual fact, however, which has been recently confirmed by a series of shaftings, is that the outcrop of the Lykens Valley bed extends west a mile beyond the limits shown on the company maps, and that instead of curving in one single line, its regularity is broken by a marked indentation, which

is caused by a prominent anticlinal. This anticlinal apparently being the same which is shown in the Mammoth bed at the water level drifts of the North Franklin No. 2 colliery. As the shaftings along the outcrop of the Lykens Valley bed in this vicinity have been accurately located by survey, there can be no doubt of the inaccuracy of the existing maps in this particular.

One of the marked features in the coal measures on this sheet is the unusual development of both of the Lykens Valley coal beds, each of which will average about 10' in thickness. Both of these beds have been extensively mined at North Franklin No. I colliery, but the workings on them are at present abandoned. Below the Mammoth, the Buck Mountain and Seven Foot have also been worked, each showing a thickness of 7'. The Mammoth as on Sheet VI and VII, appears in two separate beds.

In the workings of the rock slope at North Franklin No. 2 colliery, a coal bed is cut 112 feet under the lower member of the Mammoth, which is locally known as the Skidmore. More extended developments, however, will possibly prove that this bed is a third split of the Mammoth, with existing data, however, such a conclusion may be premature.

The thickness of each of the members of the Mammoth bed on this sheet is 12'. The beds above the Mammoth have not been worked, and have only been proven in a series of shaftings.

All the coal on these sheets is mined by the North Franklin Nos. 1 and 2 collieries, and while the sheet and district receives its name from the town of Treverton. This town is not only outside the borders of the sheet, but also beyond the borders of the coal measures. Together the North Franklin collieries 1 and 2, are known as the Treverton collieries.

CHAPTER IV.

Statistics of the Production and Shipment of Anthracite
Coal for 1885 and 1886.

The anthracite region of Pennsylvania is the most important in the States, on account of the special character of the coal which it produces; from its situation in the most thickly populated portion of the United States; and from the amount of coal which it is yearly producing. It is the most desirable domestic fuel, natural gas alone excepted, which is found anywhere and it is distributed to more widely separated markets than any other one coal; 34.62 per cent. of all the coal produced in the United States during 1886 came from the anthracite mines. The center of the region is distant from New York about 200 miles, and from Philadelphia about 125 miles, with which cities it is connected by seven distinct and independent systems of railroads and by three distinct and separate systems of water wavs.*

Unlike most of the other coal regions of the United States, particularly those east of the Rocky mountains, its coal beds are highly plicated, occurring under all degrees of dip; in some cases the beds are inverted beyond the perpendicular.

The area of maximum folding and contortion of the coal bearing measures is in the Southern and Western Middle

^{*}The information contained in this chapter was collected by the Geological Survey and prepared for publication by Mr. Ashburner; it was published by permission in the Mineral Resources of the United States for 1885 by the U. S. Geological Survey.

fields, where the occurrences of isoclinals and sharp narrow anticlinals and synclinals is most frequent. In other fields the flexures gradually become flatter, broader, and further apart toward thenorth-west. The structure in the Eastern Middle field is an apparent exception; when it is remembered, however, that in this district the flexures in the coal measures are found at a much greater height above ocean level, and the coal-basins are generally much shallower than in the Southern field, the general conclusion holds true, for the most complicated structure is invariably found in the bottoms of the coal-basins, where the squeezing of the strata was the greatest during the original plication.*

The Northern field, which is further removed from the area of maximum disturbance, is composed of a broad, canoe-shaped basin with moderate dips, the surface of any one of the coal measure strata, in general, being but slightly undulated by broad, low anticlinals and shallow synclinals, while the structure of the Loyalsock and Mehoopany field,† which is still further removed is identical with that of the Pennsylvania bituminous field; the average maximum dips of the coal bed ranging from between 3 feet in one hundred to 5 feet in one hundred.

Some idea may be had from the following table, of the depths of some of the anthracite basins in which information has been obtained, of a sufficiently definite character, to permit of estimates being made. The elevations are given in feet above ocean level:

Northern Field, Wilkes Barre basin.

	Feet.
Wilkes-Barre (L. V. R. R. depot),	+549
Mammoth bed outcrop on north side of basin, at Kings-	
ton Coal Company's slope No. 2,	+778

^{*}The difficulties which have been encountered in mining near and in the bottoms of the Lehigh basins, foreshadow the greater irregularities of structure, which will probably be met with in mining in the bottoms of the Southern field basins. Although the details of structure are rarely duplicated in different districts, yet I believe a careful mapping and study of the structural geology of the Lehigh basins will aid materially in the most economical development of the deeper portions of the Southern field basins.

[†] This field has been provisionally named the Western Northern.

Mammoth bed outerop on south side of basin, at Hollenback slope No. 2,
Eastern Middle field.
Drifton Basin.
Drifton (L. & S. R. R. depot),
Hazlelon Basin.
Hazleton (L. V. R. R. depot),
Western Middle field, Mahanoy basin.
Gilberton (P. &. R. R. depot),
Southern field, Panther Creek basin.
(Near Tamaqua).
Tamaqua (P. & R. R. R. depot),

^{*} Depth attained by workings in Prospect colliery is now over 300 feet below ocean level.

The Anthracite region has been grouped into five principal divisions, as follows:

- (1) Northern or Wyoming and Lackawanna field lies in the two valleys from which it derives its geographical name, and is embraced almost entirely by Luzerne and Lackawanna counties. A small area in the extreme north-eastern end of the field extends into Wayne and Susquehanna counties.
- (2) Eastern Middle or Upper Lehigh field, lying between the Lehigh river and Catawissa creek and principally in Luzerne county, with limited areas extending into Carbon, Schuylkill, and Columbia counties.
- (3) Western Middle or Mahanoy and Shamokin field, lying between the easternmost headwaters of the Little Schuylkill river and the Susquehanna river and within Schuylkill, Columbia, and Northumberland counties.
- (4) Southern or Pottsville field, extending from the Lehigh river, at Mauch Chunk, south-west to within a few miles of the Susquehanna river, directly north of Harrisburg, and embraced by Carbon, Schuylkill and Dauphin counties. The eastern end of this field, known as the Lower Lehigh or Panther Creek basin, between Tamaqua, on the Little Schuylkill river, and Mauch Chunk, on the Lehigh river, has generally been included by the coal trade in the Lehigh field, from the fact that its coals resemble more closely the coals obtained in the Upper Lehigh region than those in the Pottsville field west of Tamaqua, and since the shipments to market have almost entirely been made through the Lehigh Valley.
- (5) Loyalsock and Mehoopany field lies within the area drained by the headwaters of the Loyalsock and Mehoopany creeks, and is contained in Sullivan and Wyoming counties. This field is from 20 to 25 miles north-west of the western end of the northern field. Its geological structure resembles more closely that of the bituminous field, in which it has until recently been included, although the composition of many of its coals entitles them to rank with a number from the anthracite region.

Each of the above divisions are sub-divided into districts. The following table gives the name of each colliery in the region, together with its location, name of operator, shipping railroad, and production or shipment in 1884, 1885 and It also gives reference numbers by which each colliery can be found on the map of the region in the atlas accompanying this report.

The following tables give the shipments and productions in 1884, 1885, and 1886, of the collieries at work in-

Table of Areas.

No exact determination has been made of the area of the different anthracite coal basins. The general estimates contained in the following table will serve to give an idea as to their relative size:

Area and total production of individual coal fields.

Comparison		Squ I	1882.		1883.		1884.	-	1886.		1886.	Ģ.

Inspection districts.

The region is divided into seven inspection districts, as follows:

First. That portion of the Wyoming coal field included in the counties of Lackawanna, Wayne and Susquehanna.

Second. The county of Sullivan and that portion of the Wyoming coal field situated in Luzerne county east of and including Plains and Kingston townships.

Third. The remaining portion of the Wyoming coal field west of Plains and Kingston townships, including the city of Wilkes Barre and the boroughs of Kingston and Edwardsville.

Fourth. That part of Luzerne county lying south of the Wyoming coal field, together with Carbon county.

Fifth. That part of the Schuylkill coal field in Schuylkill county lying north of the Broad mountain and east of a meridian line through the center of the borough of Girardville.

Sixth. That part of the Schuylkill coal field in Schuylkill county lying north of the Broad mountain and west of a meridian line through the center of the borough of Girardville, together with Columbia, Northumberland and Dauphin counties.

Seventh. All that part of the Schuylkill coal field in Schuylkill county lying south of the Mahanoy valley and the county of Lebanon.

The shipment of coal from the three prominent coal fields into which the region has been divided by the transportation companies from the commencement of mining in 1820 has been carefully reported on by Mr. P. W. Shaefer and subsequently by Mr. John H. Jones, from whose reports the following table has been compiled.

Annual shipments of Anthracite coal in Pennsylvania since 1839, with the number of tons and percentage shipped for each region.

Total production from 1820 to 1887, 645,012,650

Under the head of Lehigh region in the above table is included the eastern end of the Southern or Pottsville coal basin between Tamaqua and Mauch Chunk. In this district which is known as the Panther Creek Coal basin, the development of the region first commenced and until 1828 more than one half of the anthracite production of the entire region came from this basin.

From 1828 to 1857, inclusive, the Schuylkill region, including the Southern coal-field, west of Tamaqua, and the Western Middle Coal-field, produced more than one-half of all the coal mined, and until 1867 this same region produced more than either one of the other two regions. In 1868 the Wyoming region took its rank as the greatest producer of the three regions, and has maintained it until now.

Since 1883, the Wyoming region, which in the above table is made to include the Lackawanna district, has produced more than one-half of the total anthracite mined.

The number of tons of coal and the percentage of the entire product mined by each of the different operating coal companies and individuals in each field and the number of tons and the precentage of the entire production handled by the different transportation companies from these same fields are shown in the following tables:—

The number of tons of coal and the percentage of the total product shipped by the different transportation companies, individually and by two or more companies combined, are shown in the following table. These statistics are generally published in the coal trade journals in a table in which a fixed tonnage is assigned to each independent company. This is not strictly correct since a number of the railroads collect from the colleries a certain amount of coal which goes to market by short lines belonging to other transportation companies. With this explanation the preceding table will be perfectly understood.

All of the transportation companies in the region, however, have relations with coal operating companies or with individual operators, by which the shipment of coal from the collieries of this company and individual operators are shipped exclusively over the respective lines controlled by the different transportation companies. The total production of coal from these collieries is given in the following tables:

Various classifications have been made of the coal produced in the anthracite fields. This subject is referred to in the Annual Report for 1885, p. 300, and in a paper read before the American Institute of Mining Engineers, see Transactions, Vol. XI, pp. 136-158, on the Classification and Composition of Pennsylvania Anthracites.

The coals from the region have been classified by Mr. Joseph S. Harris in referring to the characteristics of the coals produced from the properties of the Philadelphia and Reading Coal and Iron Company.

He refers to the coals as follows:

- (1) Hard white-ash.—"It is in great request for blast furnace and locomotive purposes, having, to an unusual degree, the qualities of resisting change of form under high heat and pressure, and, owing to its high percentage of carbon, it is valuable for producing steam; but for domestic use on a small scale, and for open-grate fires, it does not ignite readily enough to be a favorite."
- (2) Free-burning white-ash.—"The distinction between it and the hard-burning white-ash coal is that under such a fire as is ordinarily used for smelting metals or producing steam the impurities melt or clinker, which is not the case with the harder coal. This practical test is not, however, Some of the anthracites can be clinkered a very exact one. with a strong draught and with a thick bed of fire, and would, by a person who used them under such circumstances, be classed as free burning, while another, whose method of burning was more economical, would call them hard. Analysis shows that the free-burning white ash coals are quite as rich in fixed carbon, and that they have even higher heating power, as tested by the amount of water evaporated, than the harder variety, but their limited range of usefulness, which is due to their clinkering, prevents their price rising as high as the hard white-ash coals."
- (3) Schuylkill red-ash.—"It is easily ignited, easy to keep burning, and where used in open grates makes less floating dust than white-ash coal, because its ash is composed of larger particles, and on account of the oxide of

iron, which constitutes its coloring matter, has greater specific gravity than the ash of the white."

- (4) Shamokin.—"It follows in hardness and in ease of ignition next after the free burning white ash coals, and is used still more, especially for domestic purposes, its lower percentage of carbon making it ill-adapted for purposes requiring intense heat."
- (5) Lorberry red-ash.—" It burns with a little flame, and is much in request for domestic uses in the eastern markets."
- (6) Lykens Valley red-ash.—"It burns with considerable flame, is greatly liked in the eastern market for open grates, or other domestic uses, and for steam and heating purposes, wherever quick heat is required."
- (7) Trevorton or North Franklin white-ash.—"The coal is pure, but its heating properties are rather low, and it is of so friable a nature that it does not stand transportation well."
- (8) The Wyoming red-ash, (9) Lehigh red-ash, and (10) Loyalsock white-ash are not referred to in Mr. Harris's report. The Wyoming red-ash is similar in its general characteristics to the Schuylkill red-ash. The Lehigh red-ash is very similar to the hard white ash produced from the same region, with the exception of the color of the ash, due to the presence of iron, the same as in the softer red ash from Schuylkill, while the Bernice white ash, as a fuel, is rated by many coal men as being smilar to the Lykens Valley coal, except in the color of the ash. The geological structure and physical characteristics of the Bernice and Lykens Valley beds are, however, quite different.

The following table shows the amount of the different kinds of coal produced in the different fields, the number of producing collieries in each field from which the different varieties of coals come, and the proportion produced, both in tons and per cent. of total production:

		1	1884.		2	1885.		1	1-	1880.

It is found in practice that after the coal is passed through the breaker and screened into different sizes for shipment, the purity of the different sizes, as regards fixed carbon and ash, is very different. This is indicated by the following analysis of specimens collected from the Hauto screen-building of the Lehigh Coal and Navigation Company:

KIND OF COAL	Water.	Volatile mat- ter.	Fixed car- bon.	Sulphur.	Ash.	Total.	Color of ash.
Egg,	1.722 1.426 1.732 1.300	Per cent. 3.518 4.156 4.046 3.894 4.058	Per cent. 88.489 83.672 80.715 79.045 76.918	Per cent. .609 .572 .841 .697 .714	Per cent. 5.662 10.174 12.666 14.664 16.620	Per cent. 100 100 100 100 100	Light cream. Cream. Cream. Cream. Cream.

These coals are separated into different sizes according to the mesh of the screen over which they pass. The sizes noted in the above table passed over and through sieve meshes of the following dimensions:

	Through.	Over.
Broken or Grate, Rgg, Stove, Chestnut, Pea, Buckwheat,	2.5 1.75 1.25	Inches. 2.5 1.75 1.25 .73 .50

The amount of different kinds of coal under this classification produced by the different consumers and the number of collieries producing each kind of coal for 1884, 1885 and 1886, are shown in the following table:

		1884.			1885.			1886.	
CHARACTER OF COAL.	Number of col- lieries.	Production-tons.	Percentage of total produc- tion.	Number of col- lieries.	Production-tons.	Percentage of total produc- tion.	Number of col- lieries.	Production-tons.	Percentage of total produc- tion.

In the latter part of 1883 suits were entered by the Commonwealth of Pennsylvania against the various railroads and coal companies forming what was known as the trunk line pool and the coal combination for certain alleged infringements of the conditions of the charters of the companies forming these pools and violations of the State Constitution.

On the 28th of December Mr. Joseph S. Harris, president of the Lehigh Coal and Navigation Company, the oldest and one of the most important mining companies in the anthracite region, made an affadavit before the common pleas court of Dauphin county, in regard to the condition of the anthracite coal trade, the history of its development and the necessity and advantages of concerted action on the part of the mining and transportation companies.

This affidavit contains important facts of interest to the

general public. On account of its special value to parties interested in anthracite mining it is quoted in this place.

Mr. Harris says:

"The production for the year 1886 was the largest ever attained in the history of the trade, and prices have been lower during this year than the average of any year since 1862, excepting the year 1879, and, in point of fact, anthracite and bituminous coals are almost the only commodities which have not shared in the general advance of prices which have taken place during the last year. was made to secure an advance of 25 cents a ton in March 1886, but it did not prove immediately successful. incidental advantages of a large output are so great that there is always the strongest incentive to ship more coal than the market will take, and the net results of April, May and June were, with my own company, and, I believe, with the trade in general less satisfactory than for the first three months of the year. This was to some extent owing to the necessity of having contracts ahead for the sale of coal, but there was no substantial improvement in the trade until after July 1st and I believe it to be true of the whole trade, and down to that period the owners of the anthracite mines of Pennsylvania mined, transported and sold about 15,000,000 tons of that coal without getting back the cost of production and transportation, and this without any allowance for the value of coal in the ground, or interest on the capital invested.

"The mining of anthracite is attended with very large outlays of capital, especially in the Southern coal fields, in which the Lehigh Coal and Navigation Company's property is situated, where the beds of coal are of great thickness, are steeply inclined, and have been worked to great depths, so that, not counting the investment in coal lands, the money that must be spent in developing the mines alone, has for some years stood at the figure of from \$2.50 to \$3.00 per ton of annual capacity or from \$2,400,000 to \$3,000,000 for a productive capacity of 1,000,000 tons per annum. The element of expense in producing coal, which may be called "fixed cost" that is, cost which goes on whether there is any production or not, such as keeping the mines in repair, keeping the water pumped out, feeding horses and mules, paying foremen &c., is larger in mining than in almost any other business, and larger at the mines of the Lehigh Coal and Navigation Company for the reasons given, than in most other mines, having been as shown by a careful analysis, \$33,150 per month in 1884, and \$27,568 per month in 1885, or an average for these two years of say \$30,355 per month.

"If the mines are worked to a capacity of say 50,000 tons per month, this fixed cost would be a charge of \$0.607 per ton while if they are producing 120,000 tons per month, about their present capacity, the item of fixed cost would be reduced to \$0.2530 per ton, making a saving in cost of \$0.354 in this item alone.

"That this is not an exaggerated estimate is proved by the fact that in 1884, in the three months January to March inclusive, when the average monthly production was 42,823 tons. the average cost per ton was \$2.10, while for the three months September to November inclusive, the average monthly production was 98,690 tons, and the average cost \$1.38 per ton, a reduction of 72 cents per ton in cost. Again, in 1885, in the three months January to March inclusive, the average monthly production was 63,262 tons, and the average cost per ton \$1.62 while in the three months August to October inclusive, the average production was 119,630 tons, and the cost \$1.24 per ton, a reduction of 38 cents per ton; and in 1886 the average production from April to June inclusive was 67,704 tons and the cost \$1.82 per ton, while in the three months August to October inclusive, the average production was 106,675 tons, and the average cost \$1.38 per ton, a reduction of 44 cents per ton. In each year the three consecutive months of lowest production have been compared with the three consecutive months of highest production.

From this statement two results necessarily follow; that it is to the advantage of the Lehigh Coal and Navigation Company, as well as to the advantage of its customers, that it should develop its property, so that it should be capable of a large production, and that the production should be kept up as steadily as possible. The gain by large production is so

great that it is the plainest dictate of self interest to get out of the mine every ton that can be sold. Therefore this company, in common with all other companies, has gone on developing its mines until, from a monthly capacity of 67,290 tons in 1877, it reached in 1885 a monthly capacity of 118,964 tons, an increase of 77 per cent. in eight years. The growth in the demand for anthracite in the same period has risen about 51 per cent., so that it is on this account less possible now than it was eight years ago to keep the mines steadily employed.

"Careful investigation leads me to conclude that in 1883 the mines then opened had an annual productive capacity of 34,875,000 tons, and that those opened in 1884 had an annual capacity of 38,129,000 tons, while the requirement of the market in those years was 31,798,000 tons for 1883 and 30,718,000 tons for 1884, showing a surplus of capacity of 3,082,000 tons in 1883 and 7,411,000 tons in 1884, or an average for the two years of say 5,250,000 tons surplus of capacity over actual demand. This surplus capacity was not excessive, as we must be prepared at all times to meet a suddenly increased demand. The production of anthracite increased from 17,605.262 tons in 1878 to 26,142,689 tons in 1879, and when a similar increase shall again be demanded the production cannot be increased at will, nor in a short time.

"There are now, December, 1886, mines in the Hazleton region which were drowned last winter which are not yet recovered; and to open a new mine in the deeper part of the anthracite basin requires two or three years, so that no amount of capital can be relied on to increase quickly the productive capacity of the anthracite region to a great extent, and the work must be kept ahead of the demands of the market if the price is to be kept from making sudden advances. But the capacity of the mines must be kept above the average requirements, without regard to any provision for a largely increased demand, on account of the different needs of different seasons of the year. The monthly demand in the four years 1882 to 1885 inclusive, has averaged, in the three

months January to March inclusive, 1,974,000.tons, and in the three months September to November inclusive, 3,110,000 tons; whence it follows that it is necessary that mines of a monthly capacity of nearly 3,000,000 tons must be kept ready for operation, though the average monthly demand for these years was only 2,564,000 tons.

"That the mining capacity is not greatly in excess of the actual requirements is shown by the fact that in no year has there failed to be a full demand in some month for all that the mines could supply, and in some months of fullest work the stocks were drawn down. Under no system that could be devised, therefore, would it be possible to have just enough mines open to supply the demand and keep the men steadily employed.

"In this respect our present practice is much better than that which obtained years ago. The miners of the Lehigh Coal and Navigation Company, until within twenty years, had to stop work from December to the following April, four months every year, during which navigation on the canals was closed, and that they are not steadily employed is a hardship which they share with every mason, bricklayer and brickmaker in the country. Competition, by lessening profits, has compelled every mine owner to do all in his power to work his mines steadily and largely, and no pressure that can be put upon the mine owner by any governmental authority can greatly increase his desire in these respects.

"The problem that presented itself to the managers of the mining companies in 1884 was this. Under the then existing methods of working the mines, whenever the supply of coal began to press heavily upon the means of storing it, all parties suspended work, usually for three days in each week, until the demand began to draw down the visible supply. This led each producer to desire to produce as much coal as possble in the days in which work was done and thus to increase the productive capacity of his mines, until, whereas in 1881, 42 days stoppage was enough to keep the shipping collieries in working condition, in 1882, 48 days were necessary, and this grew to 60 days in 1883, and 102 days in 1884 so that one-third of the time of the

men was unemployed, and the capacity of the mines had grown to nearly 20 per cent. above the requirements of the Experience has shown that for some years back under all systems of working the larger producing interests have varied but little in the percentage of the total output provided by each, and it was thought that, if while allowing the market to take what coal it would, each party would provide but its usual share of the total, regulating its production as best might suit itself, coal could be produced cheaper, the incentive to constantly increase capacity would be lessened, the men could be more steadily employed, and the production and demand could more readily adjust themselves to each other. The different interests agreed to try this experiment for the year 1885; some parties shut up mines that could be profitably closed, and the productive capacity of the mines fell from 38,129,000 ton in 1884 to 36,482,400 tons in 1885, or from an excess over demand of 19.4 per cent. in 1884 to an excess of 13.3 per cent. in It was estimated in the beginning of the year that the market would require 30,000,000 tons of coal, but no attempt was made to keep the output below the demand, and it actually took 31,623,530 tons.

"After making allowance for the increase or diminution of the stock of coal at the shipping points, the amount which went into consumption for several years past has been as follows: In 1883, 31,606,813 tons; in 1884, 30,630,644 tons; in 1885, 31,743,666 tons, and in 1886, probably 32,250,000 tons, showing that during the last two years, in which restriction of output is charged, more coal was marketed than during the two preceding years, and in fact more than was ever marketed before.

"So, too, the amount of coal shipped by the Lehigh Coal and Navigation Company was in 1883, 907,126 tons; in 1884, 969,366 tons; in 1885, 1,068,840 tons, and will be in 1886, about 1,100,000 tons.

"That the output has never been restricted below the requirements of the market is shown by the fact that there has always been a large unsold supply on hand. In the ordinary workings of the anthracite trade every producer sells

all the coal that he can throughout the country to what is called the 'line trade' and only sells to the stocking grounds such coals as he cannot otherwise dispose of, because the coal costs about 20 cents per ton to stock and pick up, and stock coal generally sells for less than fresh mined coal. The coal in stock at any time therefore, represents the amount for which no immediate sale can be found. In 1883, this stock varied from 502.159 tons to 748,330 tons; in 1884 it varied from 588,229 tons to 885,715 tons; while in 1885 it ranged from 420.564 tons to 988,782 tons, and in 1886 from 393,202 tons to 996.946 tons, so that this average stock unsold has not diminished in the last two years.

"The price at which coal should be marketed has never been discussed at any meeting of the representatives of the anthracite producers, nor has any action ever been taken thereon at any such meeting except at the one held March 22d. 1886. The rates of transportation have never at any time been discussed, and in fact there is no concert whatever between the transporting companies as to rates except within limited areas. The greater part of the coal is carried to market at rates which are not the subject of agreement or conference between the different companies. But it is not true, as alleged in the Commonwealth's bill, that the prices of coal and of transportation have been advanced to an unjust extent or to any extent.

"In March, 1883, the rail rate on coal from Mauch Chunk to Philadelphia was \$1.80 per ton. In August 1883, this rate was advanced to \$1.90 per ton. In October 1883, it was advanced to \$2.00 per ton. In March 1884, it was reduced to \$1.80 per ton. In July 1885 it was reduced to \$1.60 per ton, and in March 1886 to \$1.50 per ton, which is the present rate; so that since the beginning of 1885 the reduction has been 30 cents per ton.

"Similarly the rate on coal from the Lehigh region to New York tide via the Central Railroad of New Jersey, which in 1883 varied from \$1.60 to \$1.67 per ton, and in 1884 from \$1.41 to \$1.64 per ton, ruled in 1885, from \$1.28 to \$1.37 per ton, and in 1886, from \$1.11 to \$1.40 per ton, showing that in the last two years the rates to New York tide were con-

siderable lower than in the previous years. To the rates here named must be added for wharfage and shipping, a sum varying in the years named from 14 cents to 20 cents, to get the free on board price, and a further sum of 15 cents to 20 cents to put the coal alongside the piers' in New York.

"As to the price realized for coal: the average price realized for the Lehigh Coal and Navigation Company's coal free on board' in New York harbor, has fallen each year since 1881, being, in that year, down to and including pea coal \$3.95 per ton, while in 1882 the average was \$3.89, in 1883 it was \$3.74, in 1884 it was \$3.48, in 1885 it was \$3.07, while in 1886 to the end of October the latest date to which accounts are completed, it is about \$2.80.

"The great fall in prices realized for coal was accompanied by a reduction in the wages of the miners of about 10 per cent but they were so much benefited by the steady work given under the present system, that the earnings per capita of the men and boys employed on the Lehigh Coal and Navigation Company's property averaged more in 1885 than in 1884, and notwithstanding all the influences that have been brought to bear on the workmen during the past year or two to make them dissatisfied, they have in the main continued steadily at work; and while they have shared with their employers lower prices, they have, as already stated, earned more per capita in the year 1885, the first of the years as to which complaint is made, than in the year 1884; and speaking from an intimate knowledge of their conditions, I assert that the community engaged in anthracite mining show from year to year that they are improving in intelligence, sobriety and material comfort.

"The reduction in cost has only been brought about by the economies which were rendered possible by concerted action. To show that the public has had at least its share of the benefits resulting from this lowering of cost, it will be sufficient to state that the profit realized on the mining of coal by the Lehigh Coal and Navigation Company in 1885, was about 28 cents per ton, which profit has fallen this year so that it will not exceed 15 cents per ton, and may not reach that amount."

LIST OF

THE PUBLICATIONS

OF THE

GEOLOGICAL SURVEY OF PENNSYLVANIA.

FROM 1874 TO 1887.

ANNUAL REPORTS.

- 1885 ANNUAL J. P. Lesley, State Geologist, 8°, 769 pp., with preface and index, accompanied by Atlas 8°, 8 pl., and maps, 1886, contains following special reports:
 - 1. Oil and Gas. John F. Carll.
 - 2. Vegetable Origin of Coal. Leo Lesquereux.
 - 3. Pittsburg Coal Region. E. V. d'Invilliers.
 - 4. Wellersburg Coal Basin. J. P. Lesley and E. B. Harden.
 - 5. Tipton Run Coal Basin. C. A. Ashburner.
 - 6. Anthracite Coal Region. C. A. Ashburner.
 - 7. Wyoming Valley Fossils. C. A. Ashburner and A. Heilprin.
 - 8. Bernice Coal Basin. C. A. Ashburner.
 - 9. Mehoopany Coal Field. F. A. Hill.
 - 10. Cornwall Ore Mines. J. P. Lesley and E. V. d'Invilliers.
 - 11. Delaware and Chester Kaolins. J. P. Lesley and C. A. Ashburner.
 - Quaternary Geology, Wyoming Valley. C. A. Ashburner, F. A. Hill, and H. C. Lewis.
 - 13. Pressure, &c., of Rock Gas. J. P. Lesley.
 - 14. Progress Geodetic Survey. Mansfield Merriman.
- 1886 ANNUAL. J. P. Lesley, State Geologist, 80, in four parts, as follows:
 - i. Pittsburg Coal Region.
 - ii. Oil and Gas Region.
 - iii. Anthracite Coal Region with Atlas.
 - iv. Miscellaneous Reports on Special Subjects. In press.

MISCELLANEOUS REPORTS.

- A. A history of the FIRST GEOLOGICAL SURVEY of Pennsylvania, from 1836 to 1858, by J. P. Lesley. With the annual reports of the Board to the Legislature for 1874 and 1875. 8°, pp. 226, 1876.
- B. Report on the MINERALS of Pennsylvania, by F. A. Genth; and on the hydro-carbon compounds, by S. P. Sadtler. With a reference map of the State. 80, pp. 206, 1875.
- B2. Report on the MINERALS, by F. A. Genth, continued from page 207 to 238. 8°, in paper cover, pp. 31, 1876. (Bound with B.)
- M. Report of Chemical Analyses in 1874-5, in the Laboratory at Harrisburg, by A. S. McCreath. 8°, pp. 105, 1875.
- M2. Report of CHEMICAL ANALYSES in 1876-8, by A. S. McCreath; Classification of coals, by P. Frazer; Fire-brick tests, by F. Platt; Dolomitic limestone beds, by J. P. Lesley; Utilization of anthracite slack, by F. Platt; Determination of Carbon in iron or steel, by A. S. McCreath. With one folded plate (section at Harrisburg) and four page plates. 8°, pp. 438, 1879.
- MS. Report of CHEMICAL ANALYSES in 1879-80, by A. S. McCreath. With a reference map of 93 iron ore mines in the Cumberland Valley. 8°, pp. 126, 1881.
- N. Report on the Levels above tide of railroads, canal and turnpike stations, mountain tops, &c., in and around Pennsylvania, in 200 tables, by C. Allen. With a map. 8°, pp. 279, 1878.
- O. CATALOGUE of specimens collected by the survey, (No. 1 to No. 4,264,) by C. E. Hall. 80, pp. 217, 1878.
- O2. CATALOGUE (continued from No. 4,265 to No. 8,974); also catalogue of fossils, (pp. 231 to 239.) 8°, pp. 272, 1880.
- P. Report on the COAL FLORA of Pennsylvania and the United States, Vols. 1 and 2, (bound together,) by L. Lesquereux. 8°, pp. 694, 1880.
- P. Report on the COAL FLORA of Pennsylvania and the United States Vol. 3, with 24 double page plates (lithographed) of coal plants, to accompany P., Vols. 1 and 2. 8°, pp. 283, 1884.
- (P.) Atlas of 87 double page plates (lithographed) of coal plants to accompany P., Vols. 1 and 2. 8°, 1879.
- P2. Report on Permo-Carboniferous plants from W. Va. and Greene county, Pennsylvania, by W. M. Fontaine and I. C. White. With 38 double page plates (lithographed). 8°, pp. 143, 1880.
- P3. Description of Ceratiocaridæ, by C. E. Beecher; and of Eurypteridæ, by James Hall. With 8 plates. 8°, pp. 39, 1884.
- Z. Report on the TERMINAL MORAINE across Pennsylvania, by H. C. Lewis; including extracts from descriptions of the Moraine in New Jersey. by G. A. Cook, and in Ohio, Kentucky and Indiana, by G. F. Wright. With a map of the State, 18 photographic views of the Moraine, and 32 page plate maps and sections. 8°, pp. lvi and 299, 1884.

GRAND ATLAS, Div. I, Pt. I, 1885, port-folio containing maps of 56 counties and parts of counties (scale 2 miles to 1 inch) on 49 sheets (26"×32".) These maps are duplicate prints on heavy paper of the county maps contained in the reports of progress.

Annual Report, 1886. Part IV.

ANTHRACITE REGION.

A2. Report on the causes, kinds and amount of WASTE in mining anthracite, by F. Platt; with a chapter on METHODS of mining, by J. P. Wetherill-

1

Illustrated by 35 figures of mining operations, a plan of the Hammond breaker, and a specimen sheet of the maps of the Anthracite coal fields. 8°, pp. 134, 1881.

- AC. Report on MINING METHODS, &c., in the anthracite coal fields, by H. M. Chance. Illustrated with 54 plates and 60 illustrations in the text. 8°, pp. 574, 1883.
- (AC.) ATLAS containing 25 plates illustrating coal mining, to accompany Report AC, by H. M. Chance. 80, 1883.
- AA. First report of progress of the anthracite survey; PANTHER CREEK BASIN, by C. A. Ashburner; with a determination of the latitude and longitude of Wilkes-Barre and Pottsville, by C. L. Doolittle; and a theory of stadia measurements, by A. Winslow. 8°, pp. 407, 1883.
- AA. Second report of progress of the anthracite survey, Part I; Statistics of Production and Shipment for 1883 and 1884. Charles A. Ashburner, geologist in charge.
- (AA.) Atlas of Southern anthracite field, Part I, containing 13 sheets; 3 geological and mine sheets, 3 cross section sheets, 3 columnar section sheets, 1 topographical map sheet, and 1 coal bed area sheet, relating to the Panther Creek basin; 1 general map of the anthracite region, and 1 chart of anthracite production from 1820 to 1881. 8°, 1882. Charles A. Ashburner, geologist in charge; A. W. Sheafer and Frank A. Hill, assistant geologists.
- (AA.) ATLAS OF WESTERN MIDDLE anthracite field, Part I, containing 11 sheets; 4 geological and mine sheets between Delano and Locust Dale, 3 topographical sheets between Quakake Junction and Mount Carmel, and 4 cross section sheets. 8°, 1884. Charles A. Ashburner, geologist in charge; A. W. Sheafer and Bard Wells, assistant geologists.
- (AA.) ATLAS OF WESTERN MIDDLE anthracite field, Part II, containing 11 sheets; 4 geological and mine sheets from Mount Carmel to the western end of the coal field, and 7 columnar section sheets covering the entire field. 8°, 1887. Frank A. Hill, geologist in charge; Bard Wells, assistant geologist.
- (AA.) ATLAS OF NORTHERN anthracite field, Part I, containing 6 geological and mine sheets between Wilkes-Barre and Nanticoke, 3 cross section sheets and 4 columnar section sheets. 8°, 1885. Charles A. Ashburner, geologist in charge; Frank A. Hill, assistant geologist.
 - (AA.) ATLAS OF NORTHERN anthracite field, Part II. In Press.
- (AA.) ATLAS EASTERN MIDDLE anthracite field, Part I, containing 8 sheets, 2 geological and mine sheets in the vicinity of Hazleton, Drifton and surrounding towns, 3 cross section sheets and 3 columnar section sheets. 80, 1885. Charles A. Ashburner, geologist in charge; A. P. Berlin and Arthur Winslow, assistant geologists.
- (AA.) ATLAS OF EASTERN MIDDLE anthracite field, Part II. In Press. Grand Atlas, Div. II, Pt. I, 1884. Port-folio containing 26 sheets, (26"× 32"), as follows: 13 sheets Atlas Southern Anthracite Field, Part I, 11 sheets Atlas Western Middle Anthracite Field, Part I, 1 sheet photo views of plaster models in Western, Middle and Southern Fields, and 1 specimen sheet, Report A 2.

Grand Atlas, Div. II, Pt. II, 1885. Port-folio containing 22 sheets, $(26" \times 32")$, as follows: 13 sheets Atlas Northern Anthracite Field, Part I, 8 sheets Atlas Eastern Middle Anthracite Field, Part I, and 1 sheet containing a preliminary general map of the Anthracite Coal Fields and adjoining counties.

For Anthracite coal in Sullivan county, see G 2 and Annual Report, 1885.

For Conglomerate beds near Carbondale, Pittston, &c., see G 5, G 7.

For Utilization of anthracite slack, see M 2.

For General description anthracite region, Quaternary Geology of the Wyoming-Lackawanna Valley, &c., &c., see Annual Report, 1885.

Annual Report, 1886. Part III.

BITUMINOUS COAL FIELDS AND SURROUNDING AREAS.

- H. First report on CLEARFIELD and JEFFERSON counties, by F. Platt. With 8 maps, 2 sections and 139 cuts in the text. 8°, pp. 296, 1875. (For second report, see II 6, H 7.)
- H 2. Report on CAMBRIA county, by F. & W. G. Platt. With 4 maps and sections and 84 cuts in the text. 8°, pp. 194, 1877.
- H 3. Report on SOMERSET county, by F. & W. G. Platt. With 6 maps and sections and 110 cuts in the text. 8°, pp. 348, 1877.
- H 4. Report on Indiana county, by W. G. Platt. With a colored geological county map and 87 cuts in the text. 80, pp. 316, 1878.
- H 5. Report on Armstrong county, by W. G. Platt. With a colored geological county map and 58 cuts in the text. 80, pp. 338, 1880.
- H 6. Second report on JEFFERSON county, (See H above), by W. G. Platt. With a colored geological county map and 57 cuts in the text. 80, pp. 218, 1881.
- H 7. Second report on CLEARFIELD county, (See H above), by H. M. Chance. With a colored geological county map, an outcrop map of the Houtzdale basin and 58 cuts in the text. 8°, pp. 197, 1884.
- I. Report on Venango county, by J. F. Carll. The geology around Warren, by F. A. Randall. Notes on the comparative geology of N. E. Ohio, N. W. Pa., and W. New York, by J. P. Lesley. With one small map of the Venango oil region, one small map of the region south and east of Lake Erie, one long section of the rocks at Warren, and 7 cuts in the text. 8°, pp. 127, 1875.
- I 2. Report of oil well records and levels in Venango, Warren, Crawford, Clarion, Armstrong, Butler, &c., by J. F. Carll. 80, pp. 398, 1877.
- 18. Report on the Venango, Warren, Clarion, and Butler Oil Regions; descriptions of rig, tools, &c.; survey of the Garland and Panama conglomerates, &c.; discussion of pre-glacial and post-glacial drainage, by J. F. Carll. With 23 page plates and an atlas. 80, pp. 482, 1880.
- (I 3.) Atlas of 22 sheets. Map of Venango county, colored geologically; map of lower oil field (Butler, Armstrong, and Clarion) in two sheets; 3 local contour maps at Franklin, Titusville and Spring Creek; two maps of N. W. Pennsylvania, showing the past and present drainage; long section across W. Pennsylvania; vertical section of the formations from the Upper Coal measures down to the bottom of the Devonian; diagram map and section of Third sand; profile section from Meadville, S. W.; 5 sheets of grouped oil well sections; 5 sheets of working drawings for well boring, &c.; diagram of daily rate of drilling six wells at Petrolia.
- I 4. Report on Warren county, by J. F. Carll. With a colored geological county map, a map of the Warren oil region, and 2 sheets of oil well sections. 8°, pp. 439, 1883. (Note—The first 147 pages of this book contain oil well records; see under Petroleum Fields below.)

1

- J. Report on the Oil Region, by H. E. Wrigley; map and profile of line of levels through Butler, Armstrong, and Clarion, by D. J. Lucas; map and profile of Slippery Rock creek, by J. P. Lesley. 5 maps and sections, a plate and 5 cuts. 8°, pp. 122, 1875.
- K. Report on GREENE and WASHINGTON counties, by J. J. Stevenson. With two county maps. (Showing the calculated local depths of the Pittsburgh and Waynesburg coal beds beneath the surface,) and 3 page plates of general sections. 8°, pp. 419, 1876. (Note.—Since the publication of this book two colored geological county Maps have been published, and will be found in pocket of volume K 3 described below.)
- K 2. First report on FAYETTE, WESTMORELAND and S. E. ALLEGHENY counties, (i. c., west of Chestnut Ridge,) by J. J. Stevenson. With 3 colored geological county maps and 50 cuts in the text. 8°, pp. 437, 1877.
- K 3. Second report on FAYETTE and WESTMORELAND counties (the Ligonier Valley), by J. J. Stevenson. With 4 page plates and 107 cuts in text. 80, pp. 331, 1878. (Note.—In a pocket in this volume will be found the colored geological maps of Greene and Washington counties alluded to above.)
- K 4. Pt. I, Report on Monongahela River coal mines, from the West Virginia State Line to Pittsburgh, (including some on the Youghiogheny and other streams), by J. Sutton Wall. With a map of the region in a pocket, 12 heliotype pictures, and 26 page plates. 80, pp. 231, 1884.
- L. Report on the Youghiogheny coke manufacture, by F. Platt; Notes on the coal and iron ore beds, by C. A. Young; Report on methods of coking by J. Fulton, (See G below); Report on the use of natural gas in the iron manufacture, by J. B. Pearse and F. Platt; The Boyd's Hill gas well at Pittsburgh, by J. P. Lesley. With a map of the coke region, two folded plates of coke ovens, and page plates and cuts in the text. 80, pp. 252, 1876.
- Q. Report on BEAVER, N. W. ALLEGHENY and S. BUTLER counties by I. C. White. With 3 colored geological county maps, and 21 page plates of sections. 80, pp. 337, 1878.
- Q 2. Report on LAWRENCE county, and special Report on Correlation of the Pennsylvania and Ohio coal beds, by I. C. White. With a colored geological county map and 234 cuts in the text. 8°, pp. 336, 1879.
- Q 8. Report on MERCER county, by I. C. White. With a colored geological county map and 119 cuts in the text. 8°, pp. 233, 1880.
- Q 4. Report on CRAWFORD and ERIE counties, by I. C. White. With two colored geological county maps and 107 cuts in the text. Also, a Report on a pre-glacial outlet for Lake Erie, by J. W. Spencer. With two maps of the Lake region. 8°, pp. 406, 1881.
- R. Report on McKean county, and its geological connections with Cameron, Elk, and Forest counties, by C. A. Ashburner. With 33 page plates of vertical and columnar sections, pictures of Rock city and Olean conglomerate, Wilcox and Kane spouting wells, map of Howard Hill coal field, &c., and an atlas of 8 sheets. 80, pp. 371, 1880.
- [](R.) ATLAS for McKean county of 8 sheets:—Colored geological county map; three topographical maps; of Buffalo Coal Company tract, Alton coal basin, and Potato Creek coal basin: map of McKean oil district; one sheet of columnar sections between Bradford and Ridgway; and 2 diagram sheets of the Well account and Production account in the Bradford district.
- R 2. Part II, report on township geology of Cameron, Elk and Forest counties, by C. A. Ashburner.
 - (R 2.) ATLAS for CAMERON, ELK and Forest counties, of 11 sheets 27

(Published November, 1884, in advance of the report):—3 colored geological county maps; 1 anticlinal and synclinal map; 1 topographical map McKean county; 2 tract maps Forest and Elk counties; 1 map Straight Creek coal basin; 2 sheets oil well sections; and 1 sheet coal sections.

V. Report on N. BUTLER county; and (Part 2) special report on the Beaver and Shenango river coal measures, by H. M. Chance. With a colored geological map of N. Butler; a contour local map around Parker; a map of the anticlinal rolls in the 6th basin; a chart of the Beaver and Shenango rivers; profile section from Homewood to Sharon; Oil well records and surface sections; and 154 cuts in the text. 80, pp. 248, 1879.

V 2. Report on CLARION county, by H. M. Chance. With a colored geological county map, a map of the anticlinals and oil-belt; a contoured map of the old river channel at Parker; 4 page plates, and 83 cuts in the text. 80, pp. 232, 1880.

For the coal basins of BRADFORD and TIOGA counties, see report G.

For the coal basins of Lycoming and Sullivan, see report G 2.

For the coal basins of POTTER county, see G 3.

For the coal basins of CLINTON county, see G 4.

For the coal in WAYNE county, see G 5.

For the East Broad Top coal basin in Huntington county, see F.

For the mountain coals in BLAIR county, see T.

For the Broad Top coal measures in Bedford and Fulton counties, see T 2.

For the coal basins in CENTRE county, see T 4.

For coal analyses, see M, M 2, M 3.

For classification of coals, see in M 2.

For coal plants, see P, P 2.

For fossil crustaceans in coal slate, see P 3.

For Origin of Coal; Pittsburgh Region and Monongahela Valley; Wellersburg coal basin, Somerset county; and Tipton Run coal-beds, Blair county; see Annual Report, 1885.

Grand Atlas Div. III, Pt. I, 1885, port-folio containing 35 sheets $(26'' \times 32'')$ as follows: 32 sheets relating to portions of the Petroleum and Bituminous Coal Fields, and three sheets relating to the Quaternary period.

Annual Report, 1886. Part I.

PETROLEUM AND GAS.

See reports I, I 2, I 3, I 4, and J, under Bituminous Coal Fields.

See L, for the Pittsburgh gas well, and the use of gas in the iron manufacture.

See Q, Q 2, Q 3, Q 4, for references to oil rocks in Beaver, Lawrence, Mercer, Crawford, Erie, and S. Butler counties.

See K for the Dunkard Creek oil wells of Greene county.

See R, R 2, for descriptions of oil rocks in McKean, Elk, and Forest counties.

See V, V 2, for notes on the oil rocks of N. Butler and Clarion counties.

See H 2 for oil boring at Cherry Tree, Cambria county.

See G 5 for oil boring in Wayne county.

See Annual Report, 1885, for report of progress in the oil and gas region, with special facts relating to the geology and physics of natural gas.

See Grand Atlas, Div. III, Pt. I, under Bituminous Coal Fields. See Annual Report, 1886. Part II.
